CONTENTS

1. EXECUTIVE SUMMARY

The Commercial Envelope Mfg. Co., Inc. (CEM) site (New York I.D. No. 152103 and EPA I.D. No. New) is an envelope manufacturing facility located on a 7-acre property approximately 0.5 mi east of the intersection of Commack Road and Grand Boulevard in the Town of Babylon, Suffolk County, New York (Figures 1-1 and 1-2, and Photos 1-16). The site is operated by Mr. Ira B. Kristel, President of CEM. The property is owned by the Town of Babylon's Industrial Development Agency, which financed the purchase of the property for CEM.

The company has operated from 1976 until the present, and reportedly generates chemical wastes such as solvents, ink, and glue. The major sources of industrial wastewater at the facility include a print-wash station, a photographic operation, and miscellaneous wash sinks. Frequent inspections and sampling by the Suffolk County Department of Health Services (SCDHS) identified three areas that contained elevated levels of solvents and heavy metals: (1) three leaching pools, (2) three ink waste storage tanks, and (3) an area adjacent to a trash compactor. It was learned during a search warrant investigation in 1985 that two leaching pools were connected to the photoroom and the printwash station by two underground pipes. An area near these leachpools, where purple-colored water was observed bubbling up through the ground, was also investigated at this time. It was established that the "bubbling-pool" was some sort of pit. At a later date, it was established that this pit was actually a third leaching pool which received wastes through a hole in a pipe which lead to the two other leach pools. This pool was found to contain approximately 1,500 gal of liquid and 31 55-gal drums of sludge. The three ink waste storage tanks, which were found to hold material enroute to the incinerator, were excavated.

Combined, the tanks were found to contain approximately 3,000 gal of liquid and 100 x 55 gal of sludge. The third area of concern, the area adjacent to a trash compactor, was filled with liquid and sludge which "oozed" out of the trash compactor as it compressed trash. A storm drain leach pool in the vicinity was found to be contaminated with solvents and metals. In 1985, following numerous court orders by SCDHS stipulating that the contaminated sites be cleaned up, two of the leaching pools were cleaned and filled with sand. The remaining pool, the ink waste storage tanks, and the storm drain near the trash compactor were cleaned in early 1986 after the company was convicted for unlawful discharge on 30 January 1986.

The preliminary HRS score for this site are as follows: Migration Score (S_M) = 37.20; Direct Contact Score (S_{DC}) = 0. The site does not pose a significant fire or explosion threat. Although two monitoring wells were installed and sampled recently for CEM at the site, they are reportedly both located downgradient of the subsurface contaminant source areas. In order to prepare a final HRS score for this site, analytical data regarding the quality of upgradient (ambient) ground water will be necessary. CEM is reportedly in the process of obtaining approval from the SCDHS for an upgradient monitoring well location. Collection and analysis of ground water from all three monitoring wells could then provide confirmation of a release of contaminants from the site to ground water (one purpose of a Phase II study). With such confirmation, the maximum attainable S_M is 37.20. The results of the monitoring well installations and future ground-water sample analyses performed for CEM should be considered and evaluated prior to developing an NYSDEC Phase II investigation. Therefore, at this time a Phase II study by NYSDEC is not recommended.

PHOTO LOG - COMMERCIAL ENVELOPE MFG. CO., INC.

Photo	Description
1-1	Southeasterly view across the front of Commercial Envelope Mfg. Co., Inc. (CEM) main building.
1-2	Southerly view across the northeast corner of the property including manhole covers of the two sanitary leach pools.
1-3	Southerly view along the northern portion of the west wall of CEM's main building.
1-4	Southerly view along the southern portion of the west wall of CEM's main building. (Note the gasoline dispensing pump near the left edge of the photo).
1-5	Northerly view toward the south side of CEM's main building (note that the grassed hill in the right center of the photo is the location of buried fuel oil storage tanks where a spill was being remediated and pumped into the tank truck in the center of this photo).
1-6	Northerly view along the eastern wall of CEM's warehouse.
1-7	View of the storage tank for CEM's incinerator. Tank is located inside main building adjacent to the incinerator.
1-8	Southwesterly view into the northeastern parking lot where the leach pools, underground storage tanks, incinerator, and dumpster/ compactor (center of photo's right edge) are located.
1-9 and 1-10	Westerly view of the northern portion of the eastern wall of CEM's main building (note the incinerator chimney near the center of the field of view). Also, note the dug up area (light colored sand and gravel) near the right side of Photo 1-10 which includes the two leach pools, the underground "cache" and the underground ink waste storage tanks (in order from the lower right area of the photo to the rollup door). Refer to Figure 1-2.
1-11	Detail of a portion of the area shown on Photos 1-9 and 1-10, including the incinerator (left portion of Photo 1-11), and the general vicinity surface area of the underground waste ink storage tanks (central portion of the photo in front of the rollup door).
1-12	Closeup view of the eastern leach pool shown on Photo 1-10 and Figure 1-2 (inset).
1-13	Closeup view of the underground "cache" located just west of the leach pool shown on Photo 1-13 and Figure 1-2 (inset).

PHOTO LOG (Cont.)

1-14 Air quality measurement of pit, later identified as third leachpool, being taken during EA's site reconnaissance.

1-15 Westerly view of the northeast corner of CEM's main building where a dumpster/compactor is located (right center of photo) in a loading bay. Fluids squeezed out of the compacted trash flow into the building-end of the loading bay where there is a storm drain.

1-16 Closeup view of the multicolored fluid observed in the building-end of the loading bay shown in the center of Photo 1-15.

2. PURPOSE

The Commercial Envelope Mfg. Co. Inc., site was listed in the New York State Registry of Inactive Hazardous Wastes Sites because of illegal hazardous waste disposal practices which occurred at the site.

The goal of the Phase I investigation of this site was to: (1) obtain available records on the site history from state, federal, county, and local agencies; (2) obtain information on site topography, geology, local surface water and ground-water use, previous contamination assessments, and local demographics; (3) interview site owners, operators, and other groups or individuals knowledgeable of site operations; (4) conduct a site inspection to observe current conditions; and (5) prepare a Phase I report. The Phase I report includes a preliminary Hazard Ranking Score (HRS) and an assessment of the available information.

3. SCOPE OF WORK

The Phase I investigation of the Commercial Envelope Mfg. Co., Inc. site involved a site inspection by EA Science and Technology, as well as record searches and interviews. The following agencies or individuals were contacted:

Contact	Information Received
Mr. Stephen J. Cohen (Site Rep) Attorney Gold and Wachtel Suite 1401 780 Third Avenue New York, New York 10017 (212) 223-3311	Site Interview

4. SITE ASSESSMENT - COMMERCIAL ENVELOPE MFG. CO., INC.

4.1 SITE HISTORY

The Commercial Envelope Mfg Co., Inc. (CEM) site is an envelope manufacturing operation located approximately 0.5 mi east of the intersection of Commack Road and the Long Island Railroad on Grand Boulevard in the Town of Deer Park, Suffolk County, New York (Figures 1-1 and 1-2). The property is owned by the Town of Babylon's Industrial Development Agency (IDA). This agency is listed on the deed as the current owner because CEM obtained a loan from the IDA to purchase the property. At present, CEM is repaying the loan. The site is operated by Mr. Ira B. Kristel, President of CEM (Appendixes 1.1-1 through 1.1-4). The envelope manufacturing firm, which has been at the site since approximately 1976, is also involved in printing and photographic operations. From the main building's construction in 1973 until 1976, the site was occupied by Alwin Seal, Inc., a company which produced such items as door frames and steel fencing (Appendixes 1.1-1 and 1.1-5).

The major sources of industrial wastewater at the facility include a printing-wash station, a photographic operation, and miscellaneous wash sinks, all of which are located in the main building (Appendix 1.1-6). A warehouse onsite, built in 1984, is used primarily for the bulk storage of paper with a small area used for job lot printing on "multilith" type machines (Appendix 1.1-7). CEM operations generate various hazardous wastes including solvents, glues, and ink. The company claimed that all such wastes were channeled into a 2,000-gal, above-ground storage tank located along the eastern wall inside the main

building. The wastewaters are then disposed of by high temperature incineration in a liquid waste disposal system located outside the building (Appendix 1.1-6). However, the Suffolk County Department of Health Services (SCDHS) has inspected the site and performed sampling many times since 1981, and has noted three areas where hazardous wastes have been disposed other than by incineration (Appendixes 1.1-3 and 1.1-8 through 1.1-12).

SCDHS personnel observed purple-colored liquid bubbling up through the ground on the east end of the building in October 1984. At that time SCDHS introduced dye in the hand-wash sink and the sump in the photo room. However, the dye did not appear in the inside waste holding tank and was not observed anywhere (Appendixes 1.1-3 and 1.1-11). On 17 June 1985, SCDHS site inspection identified a small pipe in the floor in the vicinity of CEM's "ink pot washer." A site representative comfirmed that this pipe lead beneath the floor, continued east of the building and discharged in the two eastern-most leach pools which had since been purged and backfilled with sand (Appendix 1.1-12). On 9 July 1985, a Special Investigation-Environmmental Crimes Unit from the District Attorney's office presented CEM with a search warrant to locate and dye-test pipes reportedly present in the CEM's main building and which discharged wastewater to leach pools located east of the building (Appendixes 1.1-13 and 1.1-14). Also present were representatives from the SCDHS. Dye-tests were performed along various portions of the pipes (previously plugged in some portions) originating in the "photo room" area (red dye) and the "ink pot wash machine" (green dye). Additionally, the previously purged and backfilled inline leach pool (east of the building) was reopened and excavated 6-7 ft to expose two discharge pipes. Red dye was observed to enter this leach pool through one of the discharge pipes; the green dye was not observed to enter

this leach pool. Because purple fluids had been observed to "bubble up" through the ground (about 6 ft west of the reopened leach pool), a break in the buried pipe line was suspected. Thus, an excavation was begun in that area, and uncovered a void (pit) of unknown total depth containing green- colored liquid and explosive vapors. A 4- to 6-in. diameter white pipe was observed to cross over the pit, and was discharging green-dyed liquid into the pit at a steady rate. A sample was collected from this pit when the explosive vapor concentrations lessened at the surface. Because of elevated explosive vapor concentrations and low percent oxygen measurements in the pit, the pit was not completely exposed; but rather the pit was covered with wood and the remainder of the excavation filled with sand to ground surface. Additionally, during this investigation, purple colored liquid was observed and sampled in the loading dock adjacent to the trash compactor. Analytical results of the sample collected from the pit indicate the presence of a variety of solvents (Appendix 1.1-14). In February 1986, it was determined that the pit was actually a third leach pool. Solid and liquid wastes were entering the pool through a hole in the PVC pipe which had entered the leaching pools east of this pool (Appendix 1.1-3).

The second problem area is a trash compactor situated in a loading dock on the northeast corner of the building. The area adjacent to the compactor has been observed to be filled with liquid and sludge that "oozes" out of the compactor as it compresses trash (Appendixes 1.1-3 and 1.1-14). The "ooze," which flows into a nearby storm drain pool, was found to be contaminated with solvents and metals. An overflow pool from the storm drain pool was identified but found by SCDHS to be clean (Appendix 1.1-3). The contaminated storm drain pool was

pumped out, pressure-washed, and backfilled with cement slurry (Appendixes 1.1-1 and 1.1-3). Later inspections found that the loading dock area adjacent to the compactor was again filled with contaminated liquids which were removed by a liscensed hauler (Appendix 1.1-3).

The third area of concern, located between the leaching pools and the building on the eastern side, is the three underground storage tanks intended to hold material going into the incinerator. Both the three tanks, estimated to hold 3,000 gal each, and the soil surrounding the tanks were found to be contaminated, primarily with metals, although some solvents were found in the ink waste tanks (Appendix 1.1-3).

SCDHS has also sampled two sanitary pools located on the northeast corner of CEM's main building. These pools were found to be clean (Appendix 1.1-3).

SCDHS has repeatedly initiated legal proceedings against CEM in an effort to get the three aforementioned areas cleaned up (Appendixes 1.1-8, 1.1-15, and 1.1-16). As part of one consent order, CEM applied for and received a permit to operate the high temperature incinerator (Appendixes 1.1-7, 1.1-17, and 1.1-18). In the application, it was stated that six wastewater constituents would be disposed of in this manner: lead oxide, silver salts, copper salts, iron salts, particulates, and hydrogen chloride. CEM has also been in violation for having both improper and unpermitted storage areas (Appendix 1.1-19). A SCDHS inspection of 23 September 1985 noted numerous 55-gal drums stored throughout the plant (Appendixes 1.1-20 and 1.1-21).

After several orders to clean up the pools, the two leaching pools directly connected to the "photo-room" and "ink-pot" wash machine were cleaned and filled with sand (Appendix 1.1-14). SCDHS also directed CEM to clean out the pit below the "bubbling-pool" (Appendix 1.1-22). Under a felony conviction in 1986, CEM scavenged and backfilled this pit which happened to be a third leach pool in-line with the pools that were connected to the photo room and ink-pot wash machine (Appendix 1.1-3). In addition, 3,000 gal of liquid and approximately 100 x 55 gal of sludge were removed from the three underground ink waste storage tanks. In April 1986, the three tanks and all influent pipes were filled with cement. At that time, it was also discovered that there was soil contamination along the west side of the excavation (Appendix 1.1-3). CEM has been ordered by SCDHS to remove this contamination.

In addition, it was noted during EA's site inspection, mid-January 1986, that cleaning up a recent fuel oil spill at the CEM facility was in progress. According to SCDHS, an oil distributor had mistakenly pumped 9,300 gal of fuel oil down an observation well on site (Appendix 1.1-23). CEM has since indicated that Slomins, the oil company, has to CEM's knowledge recovered the spilled oil, removed contaminated soil, and backfilled the area with sand (Appendix 1.1-1).

4.2 SITE TOPOGRAPHY

The Commercial Envelope Mfg. Co., Inc. site is located approximately 5 mi inland from Great South Bay on the southern side of Long Island at an elevation of approximately 75-80 ft above mean sea level. The regional slope of terrain is to the south (Figure 1-1). The CEM property itself is largely flat

(Figure 1-2). In the immediate vicinity of the leach pools and underground waste ink storage tank, the ground surface slopes slightly downward at about 1 percent toward the north-northwest.

The CEM facility is located in an industrial area and is adjacent to Grand Boulevard to the north and Burt Drive to the south (Appendix 1.2-1). The nearest commercial establishment is located approximately 125 ft northeast of the site. The nearest residence is approximately 1,500 ft to the south of the site. The nearest surface waterbody is Sampawans Creek and is located approximately 2,500 ft southeast of the site. However, there is no viable overland route to the surface water. The nearest well is a Suffolk County Water Authority well located approximately 0.5 mi to the northeast (Figure 1-2 and EA Site Inspection).

4.3 SITE HYDROGEOLOGY

The site is directly underlain by Pleistocene deposits of glacial outwash. This deposit is then in turn underlain by Cretaceous Age Matawan Group-Magothy Formation (undifferentiated), the Clay member and Lloyd Sand member of the Raritan Formation and finally by Precambrian Age gneiss and schist bedrock (Appendix 1.3-1). The Pleistocene deposits are approximately 180 ft in thickness (ground surface and Appendix 1.3-1) and largely comprised of stratified sand and gravel containing virtually no interstitial clay and silt. The Matawan Group-Magothy Formation (undifferentiated) locally appears to be approximately 700 ft in thickness (Appendix 1.3-1). The upper surface of this deposit is irregular because of considerable erosion during the Tertiary and Pleistocene times. Therefore, accurate prediction of formation thickness

between control points (boreholes) is difficult. This formation is generally composed of "beds and lenses of light-gray fine to coarse sand and silt, intercalated with thin to thick beds and lenses of light- to dark-gray clay, silt, and clayey/silty sand." Thin beds of lignite are commonly found in the clay and silt beds, while disseminated lignite and pyrite are common in the sand beds. Gravelly coarse sand is commonly present in the basal portion of the Magothy Formation, along with abundant interstitial clay and silt and lenses of clay, silt, and clayey/silty sand. The clay and silt beds are often apparently discontinuous lenses and not possible to correlate over significant distances as indicated on the geologic logs (Appendix 1.3-2) for seven nearby deep water supply wells: Wells S-46830 (663-ft total borehole depth) and S-31104 (658-ft total borehole depth) located 1 and 2 mi, respectively, east northeast of the site; Wells 67074 (830-ft total borehole depth) and S-18566T (653-ft total borehole depth) located about 1-1/4 and 3 mi, respectively, southeast of the site; Well S-34030 (563-ft total borehole depth) located about 2-1/2 mi west northwest of the site; Well S-23046 (451-ft total borehole depth) located about 3/4 mi southwest of the site; and Well S-59347 (515-ft total borehole depth) located about 1-3/4 mi south of the site.

The Clay Member of the Raritan Formation is estimated to be 175 ft in thickness (Appendix 1.3-1) and consists mostly of beds/lenses of light- to dark-gray clay, silt, and clayey/silty fine sand and occasional thin to thick sandy lenses of limited lateral extent. Thin beds and desseminated particles of lignite and pyrite are common in the clay portion of this unit. The Lloyd Sand Member of the Raritan Formation is estimated to be 350 ft in thickness (Appendix 1.3-1) and "consists mostly of beds and lenses of light- to

medium-gray sand and gravelly sand, commonly containing small to large amounts of interstitial clay and silt, that are intercalated with beds and lenses of light- to dark-gray clay, silt, and clayey/silty sand."

Water pumped from aquifers underlying Suffolk County is the sole source of water for public supply, agriculture, and industry (Appendix 1.3-3). The upper glacial and Magothy aquifers act as a single hydrological unit and are the only aquifers reportedly developed by wells for water supply within 3 mi of the site. Therefore, both the upper glacial and Magothy aquifers are designated as the aquifer of concern. The Lloyd aquifer, though moderately permeable (165 gpd/ft^2 estimated horizontal permeability at Brookhaven National Laboratory about 25 mi east of the site), has not been developed for water supply because more permeable aquifers are present at shallower depths, and water from the Lloyd commonly has undesireably high concentrations of iron. Additionally, the Lloyd Aquifer is overlain by the extensive, thick, low permeability (confining) Raritan Clay (Appendix 1.3-1). Therefore, the Lloyd Aquifer will not be considered further by this Phase I investigation.

The aquifers of Long Island are hydraulically interconnected and although beds and discontinuous layers of silt and clay within and between aquifers serve to confine water below them, they do not completely prevent the vertical movement of water through and around them. Soren (Appendix 1.3-1) presents data which reflect the high degree of hydraulic interconnection between the upper glacial and Magothy aquifers in the vicinity: (1) for wells completed in the upper glacial and Magothy aquifers in nearby Brentwood or Hauppauge, the head in these two aquifers decrease at a fairly uniform rate with increasing depth, and (2) water-level fluctuation in the same well groups were very similar. Soren

also reports that the estimated downward velocity of water through the Magothy aquifer in the vicinity of the ground-water divide in 1968 (along which the site is located) was 0.006 ft/day (approximately 2.2 ft/year).

Recharge to the upper glacial aquifer is derived entirely from precipitation. Recharge to the Magothy and Lloyd aquifers is derived entirely from the downward movement of water from each overlying aquifer (Appendix 1.3-4). In general, recharge to the lower aquifers occurs near the center of Long Island and discharge occurs along the edge of Long Island to the ocean and Long Island Sound. The average annual precipitation in the area is 46 inches, of which, 24 inches is estimated to infiltrate to the water table (Appendix 1.3-5). The remainder of the precipitation is returned to the atmosphere by evaporation and transpiration, except for a small amount of runoff to streams.

The upper glacial aquifer is the most permeable aquifer on Long Island with an estimated horizontal permeability of 1,000-1,500 gpd/ft^2 (Appendix 1.3-1). The site is located near the center of Long Island in an area of recharge for the underlying aquifers. In 1968, it was estimated in the region that water in the upper glacial aquifer was moving horizontally at rates less than 0.5 ft/day in areas distant from centers of pumping and to hundreds of ft/day near the screens of pumping wells (Appendix 1.3-1). The permeability of the underlying Magothy aquifer ranges widely depending upon the presence and amount of clay and silt. In 1968, it was estimated in the region that water in the Magothy aquifer was moving horizontally at rates less than 0.2 ft/day in areas distance from pumping, and to hundreds of ft/day near screens of pumping wells.

Based upon the March 1985 ground-water table contour map (SCDHS), the depth to ground water is estimated to be approximately 30 ft below ground surface, and the regional ground-water natural (unaffected by pumping) flow direction appears to be toward the south. Within 3 mi of the site, the upper glacial and Magothy aquifer of concern has been developed by 14 Suffolk County Water Authority well fields and one well each for Dix Hills Water District and Brentwood Water District (both are reportedly completed in the Magothy aquifer). The area within 3 mi of the site is served by three aforementioned water companies and a well for the Sam A. Lewison Start Center. Appendix 1.3-6 provides a list of the municipal wells located within 3 mi of the site.

4.4 SITE CONTAMINATION

Waste Types and Quantities

The envelope manufacturing company generated various hazardous chemicals including solvents, ink, and glue. Liquid and solids samples taken by the SCDHS from 1981 to 1985 from the leach pools, the ink waste storage tanks, and the areas surrounding the trash compactor, contained elevated levels of many hazardous chemicals including methylene chloride (180-2,100 ppb), 1,1,1-trichloroethane (4-150 ppb), cis-1,2-dichloroethylene (160 ppb), tetrachloroethylene (11-73 ppb) p-ethyltoluene (15-210 ppb), ethylbenzene (50-81 ppb), n-decane (40-190 ppb), toluene (93-970 ppb), xylene (55-500 ppb), 1,3,5-trimethylbenzene (12-190 ppb), decane (880 ppb), undecane (330 ppb), nonane (180 ppb), copper (0.08-865 mg/liter), iron (5-120 mg/liter), chromium (0.06-37 mg/liter), lead (0.4-166 mg/liter), and nickel (0.6-25 ppm). Sludge

samples taken near the trash compactor contained heavy metals including copper (140 mg/liter), iron (7,700 mg/liter), chromium (24 mg/liter), lead (58 mg/liter), and zinc (170 mg/liter) (Appendixes 1.1-3 and 1.1-9).

Ground Water

CEM's representative, Mr. Steven Cohen, Atty., has indicated that, in connection to a consent order entered into with SCDHS, a ground-water study at the site is being conducted by a consultant retained by CEM. Two monitoring wells (downgradient) have been installed onsite and both have been sampled. According to Mr. Cohen, the results of the sampling do not indicate whether there is any onsite contamination (analytical data was not supplied to EA). Mr. Cohen has also indicated that CEM has proposed to SCDHS the installation of an upgradient monitoring well (Appendix 1.1-1).

Surface Water

No data available.

Soil

A sample collected on 27 February 1986 from the west side of the the excavation of the ink waste storage tanks contained copper (865 ppm), total chromium (37 ppm), nickel (25 ppm), and lead (166 ppm) (Appendix 1.1-3).

Air

During EA's site inspection on 23 January 1986, air quality was measured using a photoionization detector (HNU). No measurements above background were found with the exception of the pit later identified as the third leach pool.

COMMERCIAL ENVELOPE MFG. CO., INC.
TOWN OF DEER PARK, SUFFOLK COUNTY

The Commercial Envelope Mfg. Co., Inc. (CEM) site is an envelope manufacturing facility located on a 7-acre property in the Town of Deer Park, Suffolk County, New York. Mr. Ira B. Kristel, president of CEM, operates the site. The Town of Babylon Industrial Development Agency, which financed the purchase of the property for CEM, is the current owner. CEM operated from 1976 until the present. The major sources of industrial wastewater at the facility include a print-wash station, a photographic operation, and miscellaneous wash sinks. Frequent inspections and sampling by the Suffolk County Department of Health Services (SCDHS) have identified three areas that contained elevated levels of solvents and heavy metals: (1) three leach pools, (2) three ink waste storage tanks, and (3) an area adjacent to a trash compactor. In 1985, SCDHS found that two leach pools were connected to the photoroom and the printwash station by underground pipes. It was later established that a third leach pool received wastes through a hole in a pipe which lead to the two other leach pools. This pool was found to contain approximately 1,500 gal of liquid and 31 55-gal drums of sludge. The three ink waste storage tanks, which held material enroute to the incinerator, were excavated and were found to contain approximately 3,000 gal of liquid and 100 x 55 gal of sludge. The area adjacent to a trash compactor was filled with liquid and sludge which "oozed" out of the trash compactor as it compressed trash. A storm drain leach pool in the vicinity was found to be contaminated with solvents and metals. In 1985, following numerous court orders by SCDHS stipulating that the contaminated sites be cleaned up, CEM had two of the leach pools cleaned and filled with sand. The remaining pool, the ink waste storage tanks, and the storm drain near the trash compactor were cleaned in early 1986.

Facility name: Commercial Envelope Mfg. Co., Inc.

Location: Town of Babylon, Suffolk County

EPA Region: II

Person(s) in charge of the facility: Mr. Ira B. Kristel

Grand Boulevard

Deer Park, New York 11729

Name of Reviewer: EA Science and Technology Date: 4 November 1986

General description of the facility:

(For example: landfill, surface impoundment, pile, container; types of hazardous substances; location of the facility; contamination route of major concern; types of information needed for rating; agency action, etc.)

The site is an active envelope manufacturing plant with printing and photographic operations which has been located on Grand Boulevard since 1976. Three areas at the site have been associated with hazardous waste disposal. Three leaching pools received printing ink and photo wastes containing mixed heavy metal and solvent wastes. Solvent and lead contaminated wastes from a trash compactor flowed into a storm drain. Ink wastes were held in 3 below grade storage tanks.

Scores: $S_M = 37.20$ $S_{gw} = 64.36$ $S_{sw} = 0$ $S_a = 0$

$S_{FE} = N/A$

$S_{DC} = 0$

Maximum $S_M = 37.20$

HAZARD RANKING SYSTEM

INSTRUCTIONS: As briefly as possible, summarize the information you used to assign the score for each factor (e.g., "Waste quantity = 4,230 drums plus 800 cubic yards of sludges"). The source of information should be provided for each entry and should be a bibliographic-type reference. Include the location of the document.

FACILITY NAME: Commercial Envelope Mfg. Co., Inc.

LOCATION: Town of Babylon, Suffolk County

DATE SCORED: 4 November 1986

PERSON SCORING: EA Science and Technology

PRIMARY SOURCES(S) OF INFORMATION (e.g., EPA region, state, FIT, etc.)

Suffolk County Department of Health Services
EA Site Inspection, 23 January 1986

FACTORS NOT SCORED DUE TO INSUFFICIENT INFORMATION:

Observed release to ground water
Air route

COMMENTS OR QUALIFICATIONS:

Ambient ground-water quality data are unavailable. This route is scored based on confirmed contamination in onsite leach pools, storage tanks, and a storm drain pool.

No viable overland route for surface water exists. The local fire marshal does not consider the site to be an imminent fire or explosion threat.

Direct contact score on the basis that the leach pools, the storm drain, and the ink waste storage tanks, as well as the trash compactor area, have been adequately cleaned out and covered.

GROUND WATER ROUTE

1 OBSERVED RELEASE

Contaminants detected (5 maximum):

Although monitoring wells (downgradient) have reportedly been installed at the site and samples collected and analyzed, there are no samples of ambient (upgradient) ground-water conditions.
References: 1 and 2. Assigned value = 0. Reference: 3.

Rationale for attributing the contaminants to the facility:

***

2 ROUTE CHARACTERISTICS

Depth to Aquifer of Concern

Name/description of aquifer(s) of concern:

The Pleistocene Age Upper Glacial deposits and the Cretaceous Age Magothy Formation. References: 4, 5, 6, 7, and Section 4.3 of Phase I report.

Depth(s) from the ground surface to the highest seasonal level of the saturated zone (waste table[s]) of the aquifer of concern:

30 ft. References: 8 and 16.

Depth from the ground surface to the lowest point of waste disposal/storage:

Depth of the leaching pool is 18 ft. Reference: 9. Depth to aquifer of concern is 12 ft. Assigned value = 3. Reference: 3.

Net Precipitation

Mean annual or seasonal precipitation (list months for seasonal):

Mean annual lake or seasonal evaporation (list months for seasonal):

Net precipitation (subtract the above figures):

24 inches. Reference: 7. Assigned value: 3. Reference: 3.

Permeability of Unsaturated Zone

Soil type in unsaturated zone:

Sand and gravel. References: 4, 5, 6, 7, and Section 4.3 of Phase I report.

Permeability associated with soil type:

$>10^{-3}$ cm/sec. Assigned value = 3. Reference: 3.

Physical State

Physical state of substances at time of disposal (or at present time for generated gases):

Liquid and sludge. References: 9 and 10. Assigned value = 3. Reference: 3.

***

3 CONTAINMENT

Containment

Method(s) of waste or leachate containment evaluated:

Unlined leaching pools, storm drain near compactor, leaking ink waste storage tanks. Reference: 9.

Method with highest score:

All of the above. Assigned value = 3. Reference: 3.

4 WASTE CHARACTERISTICS

Toxicity and Persistence

Compound(s) evaluated:

Chloroform, copper, iron, chromium, cadmium, lead, nickel.
References: 9 and 10.

Compound with highest score:

Chloroform, copper, iron, chromium, cadmium, and lead all = 18.
Reference: 3.

Hazardous Waste Quantity

Total quantity of hazardous substances at the facility, excluding those with a containment score of 0 (Give a reasonable estimate even if quantity is above maximum):

1,500 gal of liquid and 1,700 gal of sludge were removed from a leaching pool and 3,000 gal of liquids and 5,500 gal of sludge were removed from the ink waste storage tanks. Reference: 9.

Basis of estimating and/or computing waste quantity:

Based on the material removed, quantity = 11,700 gal.
Assigned value = 2. Reference: 3.

***

5 TARGETS

Ground Water Use

Use(s) of aquifer(s) of concern within a 3-mile radius of the facility:

Drinking water with municipal water from alternate sources presently available. References: 12, 13, 14, and 15. Assigned value = 2.
Reference: 3.

Distance to Nearest Well

Location of nearest well drawing from aquifer of concern or occupied building not served by a public water supply:

Suffolk County Water Authority well located on Industry Court.
References: 12 and 13.

Distance to above well or building:

Approximately 3,200 ft. Reference: 12. Assigned value = 3.
Reference: 3.

Population Served by Ground Water Wells Within a 3-Mile Radius

Identified water-supply well(s) drawing from aquifer(s) of concern within a 3-mile radius and populations served by each:

Community Supplies:	Population:
Suffolk County Water Authority's Patchogue, Babylon, and Bayshore Water Districts	389,443
Brentwood Water District	26,000
Dix Hills Water District	29,415
Sam A. Lewison Start Center	40
	444,898

(Appendix A1.3-6 provides a list and description of wells.)
References: 12-15 and 26-28.

Computation of land area irrigated by supply well(s) drawing from aquifer(s) of concern within a 3-mile radius, and conversion to population (1.5 people per acre):

Approximately 186 acres of land are used for agricultural purposes within a 3-mi radius of the site. However, irrigation wells on agricultural land in Suffolk County are not registered by any regulatory agency, so there are no lists or descriptions of the locations of these wells.

References: 17, 18, 19, 20, and 21.

Total population served by ground water within a 3-mile radius:

444,898. Assigned value = 5. Combined value = 35. Reference: 3.

SURFACE WATER ROUTE

1 OBSERVED RELEASE

Contaminants detected in surface water at the facility or downhill from it (5 maximum):

No data available. Reference: Chapter 3.
Assigned value = 0. Reference: 3.

Rationale for attributing the contaminants to the facility:

***

2 ROUTE CHARACTERISTICS

Facility Slope and Intervening Terrain

Average slope of facility in percent:

Approximately 1 percent. Estimated with Suunto clinometer. Reference: 11, and Figure 1-2 of the Phase I Report.

Name/description of nearest downslope surface water:

Sampawams Creek. Reference: 16.

Average slope of terrain between facility and above-cited surface water body in percent:

0.9 percent slope. Estimated using a Suunto clinometer and from the topographic map. References: 11 and 16.

Is the facility located either totally or partially in surface water?

No. References: 11 and 16.

Is the facility completely surrounded by areas of higher elevation?

No. References: 11 and 16. Assigned value = 0. Reference: 3.

1-Year, 24-Hour Rainfall in Inches

2.5 inches. Assigned value = 2. Reference: 3.

Distance to Nearest Downslope Surface Water

Approximately 2,500 ft. Reference: 16. Assigned value = 2. Reference: 3.

Physical State of Waste

Liquid and sludge. References: 9 and 10. Assigned value = 3. Reference: 3.

***

3 CONTAINMENT

Containment

Method(s) of waste or leachate containment evaluated:

All wastes were channeled to the leach pools and storm drains. There is no viable surface water route. Also, the area adjacent to the trash compactor is an old loading dock (enclosed basin). Reference: 11.

Method with highest score:

Intervening terrain precludes runoff from entering surface water. Assigned value = 0. Reference: 3.

4 WASTE CHARACTERISTICS

Containment is zero. Therefore, waste characteristics are not scored. Reference: 3.

Toxicity and Persistence

Compound(s) evaluated

Compound with highest score:

Hazardous Waste Quantity

Total quantity of hazardous substances at the facility, excluding those with a containment score of 0 (Give a reasonable estimate even if quantity is above maximum):

Basis of estimating and/or computing waste quantity:

***

5 TARGETS

Surface Water Use

Use(s) of surface water within 3 miles downstream of the hazardous substance:

Recreational. Reference: 22. Assigned value = 2. Reference: 3.

Is there tidal influence?

No. Reference: 16.

Distance to a Sensitive Environment

Distance to 5-acre (minimum) coastal wetland, if 2 miles or less:

None. Reference: 16.

Distance to 5-acre (minimum) freshwater wetland, if 1 mile or less:

None. Reference: 16.

Distance to critical habitat of an endangered species or national wildlife refuge, if 1 mile or less:

None. Reference: 23. Assigned value = 0. Reference: 3.

Population Served by Surface Water

Location(s) of water supply intake(s) within 3 miles (free-flowing bodies) or 1 mile (static waterbodies) downstream of the hazardous substance and population served by each intake:

None. References: 5, 14, 17, and 18.

Computation of land area irrigated by above-cited intake(s) and conversion to population (1.5 people per acre).

None. The major source of irrigation water in Suffolk County is ground water from wells. Generally, surface water is not utilized for this purpose. Reference: 17 and 18.

Total population served:

Zero. References: 14, 17, and 18. Assigned value = 0. Reference: 3.

Name/description of nearest of above waterbodies:

Distance to above-cited intakes, measured in stream miles.

AIR ROUTE

1 OBSERVED RELEASE

Contaminants detected:

During EA's site inspection on 23 January 1986, air quality was measured using a photoionization detector (HNU). No measurements above background were found with the exception of the pit later identified as the third leach pool. EA has researched all agency files and has found no data indicating a release to air (Chapter 3). Assigned value = 0. Reference: 3.

☐ A. EPA ☐ B. EPA CONTRACTOR ☐ C. STATE ☒ D. OTHER CONTRACTOR ☐ E. LOCAL HEALTH OFFICIAL ☐ F. OTHER: _____ (Specify)

CONTRACTOR NAME(S): EA Science and Technology

02 SITE STATUS (Check one)	03 YEARS OF OPERATION
☒ A. ACTIVE ☐ B. INACTIVE ☐ C. UNKNOWN	1976 (BEGINNING YEAR) present (ENDING YEAR) ☐ UNKNOWN

04 DESCRIPTION OF SUBSTANCES POSSIBLY PRESENT, KNOWN, OR ALLEGED

Printing ink and photo wastes containing mixed heavy metal and solvent wastes discharged to leaching pools. Solvent and lead-contaminated wastes from a trash compactor flowed into a storm drain. Ink wastes were held within below grade tanks. Discharge to a discovered underground "cache" still active,*

05 DESCRIPTION OF POTENTIAL HAZARD TO ENVIRONMENT AND/OR POPULATION

Potential ground-water contamination problem resulting from several years discharge of printing ink and photo waste containing mixed heavy metal and solvent wastes.

V. PRIORITY ASSESSMENT

01 PRIORITY FOR INSPECTION (Check one. If high or medium is checked, complete Part 2 - Waste Information and Part 3 - Description of Hazardous Conditions and Incidents)

☐ A. HIGH (Inspection required promptly) ☐ B. MEDIUM (Inspection required) ☐ C. LOW (Inspect on time available basis) ☐ D. NONE (No further action needed, complete current disposition form)

PART 3 - DESCRIPTION OF HAZARDOUS CONDITIONS AND INCIDENTS

I. IDENTIFICATION	
01 STATE	02 SITE NUMBER
NY	New

II. HAZARDOUS CONDITIONS AND INCIDENTS

01 ☒ A. GROUNDWATER CONTAMINATION
03 POPULATION POTENTIALLY AFFECTED: 444,898
02 ☐ OBSERVED (DATE: _____) ☒ POTENTIAL ☐ ALLEGED
04 NARRATIVE DESCRIPTION

Ground water in the aquifer of concern is the water source for 14 SCWA well fields, 1 Dix Hills Water District well, and 1 Brentwood Water District well, and the Sam A. Lewison Start Center.

01 ☐ B. SURFACE WATER CONTAMINATION
03 POPULATION POTENTIALLY AFFECTED: _____
02 ☐ OBSERVED (DATE: _____) ☐ POTENTIAL ☐ ALLEGED
04 NARRATIVE DESCRIPTION

No viable overland route to surface water.

01 ☐ C. CONTAMINATION OF AIR
03 POPULATION POTENTIALLY AFFECTED: _____
02 ☐ OBSERVED (DATE: _____) ☐ POTENTIAL ☐ ALLEGED
04 NARRATIVE DESCRIPTION

None known.

01 ☐ D. FIRE/EXPLOSIVE CONDITIONS
03 POPULATION POTENTIALLY AFFECTED: _____
02 ☐ OBSERVED (DATE: _____) ☐ POTENTIAL ☐ ALLEGED
04 NARRATIVE DESCRIPTION

No imminent threat.

01 ☐ E. DIRECT CONTACT
03 POPULATION POTENTIALLY AFFECTED: _____
02 ☐ OBSERVED (DATE: _____) ☐ POTENTIAL ☐ ALLEGED
04 NARRATIVE DESCRIPTION

None known.

01 ☒ F. CONTAMINATION OF SOIL
03 AREA POTENTIALLY AFFECTED: Unknown (Acres)
02 ☒ OBSERVED (DATE: 2/27/86) ☐ POTENTIAL ☐ ALLEGED
04 NARRATIVE DESCRIPTION

Soil contamination was discovered along the west side of the ink waste storage excavation and contained high concentrations of copper, chromium, nickel, and lead.

01 ☐ G. DRINKING WATER CONTAMINATION
03 POPULATION POTENTIALLY AFFECTED: 444, 898
02 ☐ OBSERVED (DATE: _____) ☐ POTENTIAL ☐ ALLEGED
04 NARRATIVE DESCRIPTION

Limited to the population served by ground water from the aquifer of concern within a 3-mile radius of the site.

01 ☐ H. WORKER EXPOSURE/INJURY
03 WORKERS POTENTIALLY AFFECTED: _____
02 ☐ OBSERVED (DATE: _____) ☐ POTENTIAL ☐ ALLEGED
04 NARRATIVE DESCRIPTION

None known.

01 ☐ I. POPULATION EXPOSURE/INJURY
03 POPULATION POTENTIALLY AFFECTED: _____
02 ☐ OBSERVED (DATE: _____) ☐ POTENTIAL ☐ ALLEGED
04 NARRATIVE DESCRIPTION

None known.

I. IDENTIFICATION
01 STATE: NY | 02 SITE NUMBER: New

II. HAZARDOUS CONDITIONS AND INCIDENTS (Continued)

01 ☐ J. DAMAGE TO FLORA
02 ☐ OBSERVED (DATE: _____) ☐ POTENTIAL ☐ ALLEGED
04 NARRATIVE DESCRIPTION

None known.

01 ☐ K. DAMAGE TO FAUNA
02 ☐ OBSERVED (DATE: _____) ☐ POTENTIAL ☐ ALLEGED
04 NARRATIVE DESCRIPTION (Include name(s) of species)

None known.

01 ☐ L. CONTAMINATION OF FOOD CHAIN
02 ☐ OBSERVED (DATE: _____) ☐ POTENTIAL ☐ ALLEGED
04 NARRATIVE DESCRIPTION

None known.

01 ☒ M. UNSTABLE CONTAINMENT OF WASTES (Spills/Runoff/Standing liquids, Leaking drums)
02 ☒ OBSERVED (DATE: 1984-1986) ☐ POTENTIAL ☐ ALLEGED
03 POPULATION POTENTIALLY AFFECTED: _____
04 NARRATIVE DESCRIPTION

The leaching pools were unlined and contained sludge and standing liquid. The contents of the pits were sampled and found to contain various solvents and metals.

01 ☐ N. DAMAGE TO OFFSITE PROPERTY
02 ☐ OBSERVED (DATE: _____) ☐ POTENTIAL ☐ ALLEGED
04 NARRATIVE DESCRIPTION

None known.

01 ☐ O. CONTAMINATION OF SEWERS, STORM DRAINS, WWTPs
02 ☐ OBSERVED (DATE: _____) ☐ POTENTIAL ☐ ALLEGED
04 NARRATIVE DESCRIPTION

None known.

01 ☒ P. ILLEGAL/UNAUTHORIZED DUMPING
02 ☒ OBSERVED (DATE: 1984-1986) ☐ POTENTIAL ☐ ALLEGED
04 NARRATIVE DESCRIPTION

Commercial Envelope was in violation over a period of several years for illegally discharging hazardous chemicals into three leach pools, a storm drain, and three ink waste storage tanks.

05 DESCRIPTION OF ANY OTHER KNOWN, POTENTIAL, OR ALLEGED HAZARDS

II. ENFORCEMENT INFORMATION

01 PAST REGULATORY/ENFORCEMENT ACTION ☒ YES ☐ NO

02 DESCRIPTION OF FEDERAL, STATE, LOCAL REGULATORY/ENFORCEMENT ACTION

Suffolk County Department of Health Services has repeatedly initiated legal proceedings against Commercial Envelope. The consent orders have stipulated that all contaminated areas be cleaned, observation wells be installed, and a ground-water quality study be initiated. In 1986, the areas were cleaned and the monitoring wells were installed.

Section 3.
Appendixes 1.1-3, 1.1-4, 1.1-8, 1.1-15, and 1.4-1

EPA FORM 2070-13 (7-81)

6. ASSESSMENT OF DATA ADEQUACY AND RECOMMENDATIONS

6.1 ADEQUACY OF EXISTING DATA

The available data are considered insufficient to prepare a final HRS score for the Commercial Envelope Mfg. Co., Inc. site. There is documentation of onsite hazardous waste disposal in underground tanks and leach pools which have reportedly been cleaned out and backfilled with clean sand. Although two monitoring wells were installed recently for CEM at the site, they are reportedly both located downgradient of the aforementioned subsurface contaminant source areas. Therefore, although ground-water samples have reportedly been collected and analyzed by CEM's consultant, there are no samples of ambient (upgradient) ground-water conditions.

6.2 RECOMMENDATIONS

In order to prepare a final HRS score for this site, analytical data regarding the quality of upgradient (ambient) ground water will be necessary. CEM is reportedly in the process of obtaining approval from the SCDHS for an upgradient monitoring well location. Collection and analysis of ground water from all three monitoring wells by CEM's consultant could then provide confirmation of a release of contaminants from the site to ground water (one purpose of a Phase II study). The results of the monitoring well installations and future ground-water sample analyses performed for CEM should be considered and evaluated prior to developing an NYSDEC Phase II investigation. Therefore, at this time a Phase II study by NYSDEC is not recommended.

Re: Commercial Envelope Manufacturing Co., Inc. ("CEM")
I.D. Number 152103

Dear Ms. Ligotino:

As you know, we are the attorneys for CEM. This letter shall serve as the formal revision to the Interview Acknowledgement Form ("IAF"), dated January 23, 1986, which must be included in your Phase I report to the New York State Department of Environmental Conservation.

Page One of IAF

CEM took possession of the property at 900 Grand Boulevard, Deer Park, New York in 1976, but the property is owned by the Town of Babylon. CEM is owned by the Kristel family.

The three below-grade ink waste holding tanks were properly abandoned pursuant to Article 12 of the Suffolk County Sanitary Code. The waste from the tanks was removed and the tanks were filled with concrete. A copy of the SCDHS report confirming the proper abandonment of the tanks, dated April 4, 1986, is enclosed herewith.

We are unaware of the basis for your statement in the last sentence on Page one of the IAF.

Page Two of IAF

There are no groundwater discharges at the site other than sanitary septic tank wastes at this time. A groundwater study is currently being conducted by the groundwater consultants we retained in connection with the consent order entered into between CEM and SCDHS. Two monitoring wells have been installed on site and the wells have been sampled. The results do not indicate whether there is any on-site contamination. Accordingly, we proposed to the SCDHS the installation of a third well at an upgradient location off-site. We are awaiting the response of the SCDHS to this proposal.

All of the drums stored on site have been placed in containment areas in accordance with Article 12 of the Suffolk County Sanitary Code. The SCDHS has inspected the storage/containment facility and has verified the Article 12 compliance by CEM.

The waste from the two leaching pools and the "cache" was pumped out, cleaned up and filled to grade with clean sand in accordance with the consent order.

With respect to the fuel oil spill referred to in the fourth paragraph, Slomins, the oil company, has to our knowledge recovered the spilled oil, removed the contaminated soil and backfilled the area with sand.

The incinerator on site is operating under a permit issued by the proper regulatory authorities.

Very truly yours,

Steven J. Cohen

RE: Commercial Envelope, Inc.

Dear Mr. Cohen:

Thank you for taking the time to provide EA Science and Technology with information on the history of the above site. In order to compile an accurate report on this site, we request that you carefully read and sign the attached Interview Acknowledgement Form, which we expect to include in our Phase I report. This is an important verification document that is required by our contract with the New York State Department of Environmental Conservation.

If you wish to correct or update our interview summary, please do so in the space provided and affix your signature and date to the attached form following your revisions. If you need additional space, enclose your own signed and dated attachments.

Please return the signed acknowledgement form within 10 days in the stamped, self-addressed envelope provided.

If you have any questions, please do not hesitate to call. Thank you for your prompt reply.

Sincerely,

Rebecca Ligotino

Interview Summary:

Commercial Envelope Mfg. Co., Inc. purchased the property at 900 Grand Boulevard, Deer Park, New York in 1976. The company, owned by Steven Crystal, manufactures envelopes and uses several potentially hazardous substances including solvents, glues, and ink. All liquid wastes are channeled through a 2,000-gallon holding tank inside the plant, and then incinerated on site. The property has been under close scrutiny by the Suffolk County Department of Health Services (SCDHS), and a dye test performed indicated that the system was not fully connected as the dye eventually migrated to the leaching pools. As a result, the SCDHS issued a Consent Order to clean up the site, install three monitoring wells, and bring the industrial waste holding tank and incinerator on site into compliance with applicable state regulations.

There are four problem areas that the SCDHS has identified on site. There are two leaching pools east of the building that are connected via two pipes to the "pot-wash" area and "photo-rooms" inside the building. The connection between the leaching pools and the "photo-room" was apparently plugged at one time, but was found to be leaking during a SCDHS inspection. These leaching pools were scavenged and filled in with sand. The second problem area is a trash compactor situated on a loading dock on the northeast corner of the building. The compactor compresses trash, and the resulting "ooze" flows into the loading dock storm drain. The SCDHS believes this "ooze" has been solvent and lead contaminated. The storm drain was scavenged and cleaned up. The sludge was pumped out, and then the area was pressure-washed several times. The pool was filled with a cement slurry. The consulting firm of H2M assisted in this clean up. A second overflow pool to the storm drain was identified, but found by SCDHS to be clean. A third area of concern is the three below grade ink waste holding tanks, intended to hold material going into the incinerator. These three tanks are assumed by SCDHS to be steel with a cement collar and a manhole cover. The tanks probably hold 3,000+ gallons each, and are interconnected. The waste in these tanks was not removed, however, the tanks have been backfilled in by Commercial Envelope with sand. When they were originally pumped out, the liquid was discharged into a field forming a "purple lake."

The fourth potential problem was identified by the SCDHS, during a July 1985 inspection, when they observed liquid leaking from a broken pipe into a 6- to 8-ft deep hole. A sample to be analyzed for metals and organics was collected by SCDHS and the hole was closed. However, during EA's site reconnaissance, a small diameter hole to the surface was observed. The pipe suspected to be leaking to this area is from the "pot wash" area and has been cut and cemented in.

There are numerous 55-gallon drums stored on site and throughout the plant. These drums hold glues and ink, and will eventually be poured into a 2,000-gallon holding tank inside the plant. Wastes are discharged from the tank to the incinerator and burned. The SCDHS has ordered that the drums be stored in two areas rather than throughout the plant.

The bathrooms on the site are connected to sanitary pools, and SCDHS inspection found the pools to be clean.

Mr. Cohen did not know if the underground ink waste storage tanks, the underground waste storage "cache", and the two leach pools located immediately east of the "cache" were installed by the previous occupant or by Commercial Envelope. However, the storm drain and associated leach pools were apparently installed prior to Commercial Envelope's purchase of the property in 1976. There are two 10,000-gallon, underground storage tanks on site; one containing gasoline and the other fuel oil. In mid-January 1986, there was a fuel oil spill when an oil distributor pumped too much fuel into one of the tanks.

Commercial Envelope Mfg. Co., Inc. has filled in most of the problem areas with sand in efforts to clean up the site. The three monitoring wells are proposed by Commercial Envelope to be installed to first water. There has been no testing of the incinerator smokestack as air monitoring was not ordered by the SCDHS.

The previous occupant at the facility was Alvin Seal, Inc., whose product line included items such as door frames and steel fencing. It is unknown if the manufacture or assembly of products occurred on site.

DATE 4/9/86 | TIME Am | (ORIG) PERIODIC RE | (NO WASTE) WASTE H&H | SEWAGE SYSTEM PUBLIC (PRIVATE)

Additions + Corrections

(1) On January 30, 1986, the above company pled guilty to one count of Unlawful Discharge of Hazardous Waste in the Second Degree, a class E felony under the NYS Environmental Conservation law, and 100 violations of Section 1217 of the Suffolk County Sanitary Code. On 1/30/86, the company was sentenced to pay a fine of $25,000.00 to the hazardous waste remedial fund under its felony conviction, and an additional $25,000.00 to the County of Suffolk under the Sanitary Code convictions.

(2) Area below "bubbling pool," was scavanged by Chemical Pollution Control starting on Feb. 28, 86. Area below was a typical 3 ring leaching pool with a cement dome on top, the rings were approx. 12 ft across + the hole was approx. 18 ft. deep. The physical appearance was that a hole had been chopped thru a side wall of the dome (Southern edge.) + a hole in the PVC pipe entering the leaching pools East of this pool allowed solids + liquid to enter the pool, no other means of waste entering the pool were discovered.

Chemical Pollution Control (CPC) removed approx. 1500 gal. of liquid + 31 x 55 gal. of sludge from the pool.

Sample of sludge 3PO 2/27 revealed Cu = 68.0 ppm, tot Chromium 210 ppm, Nickel 16.0 ppm, Lead 27.0 ppm, Cadmium < 1.5 ppm, Silver < 1.5 ppm. (analysis sheet attached).

(3) 3/4/86 - CPC filled in leaching pool below "bubbling pool" with clean sand to grade.

(4) The three under ground INK waste tanks located on the East side of Commercial were found to still contain industrial waste. Approx. 3000 gal. of liquid + approx. 100 x 55 gal. of sludge.

On Friday, 4/4/86 the three tank were filled in with cement + all influent pipes plugged with cement.

(5) Additional soil contamination was discovered along the West side of the excavation around the ink waste tanks. (1D03/27) The analysis revealed; Copper 865.0 ppm., tot Chromium 37.0 ppm, Nickel 25.0 ppm, Lead 1660.0 ppm., Cadmium. ∠2.2, Silver ∠2.2, by EPA soil analysis.

Commercial Envelope Mfg has been ordered by SCDHS to remove this contamination.

(6) Area around + below the trash compactor on the East side of the B16. was again filled with liquid industrial waste which was removed by CPC.

DAVID GERLING PHS.

Correction

NOTE: 2nd Para. There are three leaching pools located on the East side of Commercial Envelope Mfg Corp. all three were receiving industrial waste.

David Gerling PHS

Communications Summary: Re: Commercial Envelope

Dave called regarding the Interim Acknowledgement Form. He questioned our indication that Steven Crystal is the owner. He believes it is Ira Crystal, Steven's father. I told him we would check on this. Since the site recon, there has been a conviction and clean-up work at the site. Drums of material have been removed. The ink waste holding tanks have been cleaned out and filled with cement. The loading dock area was scavengered again. From the "filled in" pools — 3,000 gal of industrial waste liquids and ~150 drums of sludge were removed. The "Castle" was opened and scavenged. It was found to be a 3rd leaching pool. Removed 10's of drums of sludge of blue-black ink wastes.

(see over for additional space)

Signature: Rebecca Lightner

Dave will update IAF and send it along with analytical data.

Babylon Town Hall - Building Dept., investigation of Commercial Envelope Mfg Corp. as per building Permits/or construction plans.

The orginal building was constructed in 1973 and the original tenant was a firm called Nu-Seal Inc., they occupied the building until approx 1978 when Commercial Envelope moved into the site.

Of special note: there are two (2) large underground tanks at site, originally they held fuel oil, however the use on one tank was changed to hold gasoline. At the facility now there are two 10,000 gal. tanks, 1 holds fuel oil the 2nd holds gasoline.

Of special note: On construction plans obtained at Babylon Town Bldg. Dept. Industrial Chemical + Air Pollution Survey, 12/7/79, signed by Inv. B. Kingsley received the time;

Re: Commercial Envelope Mfg. Co.
Air Permit

Dear Mr. Soderberg:

Enclosed is a completed application to operate a high-temperature incinerator at the Commercial Envelope facility in Deer Park.

There are now no liquid waste discharges to ground at this plant, other than sanitary wastewaters.

Yours truly,

HOLZMACHER, McLENDON & MURRELL, P.C.

ESTIMATE OF EMISSIONS

COMMERCIAL ENVELOPE MFG. CO., INC.

General Information

Commercial Envelope Manufacturing Co., Inc. is engaged in the business of producing and printing envelopes. The major sources of industrial wastewater at this facility include a printing-wash station, photo laboratory and miscellaneous wash sinks. The current wastewater flows from these sources are estimated to total approximately 750 gallons per day. These non-hazardous wastewaters are accumulated within the facility building in a 2000-gallon capacity, above-ground storage tank. The wastewaters are disposed of by high-temperature incineration in a liquid waste disposal system.

In order to determine the "emission rate potential" (ERP) from the liquid waste disposal system, several samples of the liquid waste were analyzed during the period of December 1984 through February 1985. Based on these analytical data, the characteristics of the wastewater fed to the incinerator and the emissions were estimated. Details of these computations are presented below.

Computations

Number of hours of system* operation per day	24 hours
Number of days of system operation per week	5 days
Number of weeks of system operation per year	50 weeks
Design wastewater feed rate to the system	0.67 GPM
Design wastewater feed rate to the system per hour	40 gallons

*System = waste disposal system

Estimated Emissions:

Wastewater Constituent	Estimated* Maximum Concentration (mg/l)	Input to Liquid Disposal System (lbs/hr)	Actual Emissions (lbs/hr)	Emission Rate Potential (ERP) (lbs/hr)	Actual Emissions (lbs/yr)
Lead Oxide (as Pb)	3.0	1.00×10^{-3}	1.00×10^{-3}	1.00×10^{-3}	6.0
Silver Salts (as Ag)	2.8	9.30×10^{-4}	9.30×10^{-4}	9.30×10^{-4}	5.61
Copper Salts (as Cu)	31.2	1.04×10^{-2}	1.04×10^{-2}	1.04×10^{-2}	62.5
Iron Salts (as Fe)	193.0	6.44×10^{-2}	6.44×10^{-2}	6.44×10^{-2}	386.6
Particulates**	3928.0	1.31	1.31	1.31	7867.0
Hydrogen Chloride***	Traces	2.30×10^{-4}	2.30×10^{-4}	2.30×10^{-4}	1.38

*Based on four sets of analytical data. The concentration data presented are the maximum detected levels.

**Assumed to be generated from the dissolved and suspended solids content of the wastewater.

***Assumed to be generated from the combustion of trace quantities of volatile halogenated organic compounds present in the wastewater. This includes methylene chloride (0.37 mg/l max.) and tetrachloroethylene (0.42 mg/l max.).

Re: Commercial Envelope
Mfg. Co. Warehouse

I

Dear Mr. Akras:

Pursuant to your telephone request, I am reporting on the occurrence of hazardous materials in the new "warehouse" of our client, Commercial Envelope Mfg. Co.

I visited the premises yesterday afternoon, unannounced. Walk-through was made once alone, and again with the plant manager. Thus, I am confident that I saw all that was to be seen.

The structure is a 85,000 square foot Butler "prefab" metal building, erected on a concrete pad. It is used primarily for the bulk storage of paper. A small area is used for job-lot printing, on "multilith" type machines. There are no floor drains or wash down facilities.

The following materials were found:

1. 3X55 gal. drums, on pallet
   Derruchem Industrial Degreaser
   These drums belong to the contractor, and Commercial Envelope is awaiting their pick-up and removal.

2. 1X55 gal. drum, with hand operated metering pump, on pallet
   Multilith Blankrola Solvent (perchloroethylene and petroleum naptha)
   This is a working drum. The pump dispenses approximately one quart, and is used to fill a small plastic bottle with solvent, used to clean the multilith press rollers.

3. 1X55 drum, with hand operated metering pump, on pallet
   Varn Planket and Roller Wash, V-133
   This has the same use as item 2, above

4A 2X55 gal. drums, on pallet
D.T.E. Heavy Medium (Mobil Oil Co.)

4B 2X55 gal. drums with pump dispenser, on pallet
Ethylene glycol antifreeze

4C 1X55 gal. drum, on pallet
Dextron #2 transmission fluid

4D 1X55 gal. drum with pump dispenser, on pallet
SAE 40 motor oil

(The above drums are working quantities of fluids used in the company's vehicles.)

5. Approximately two dozen X 5 gal. pails, on floor around presses
Multilith ink
These are inks used on the presses. Although I do not have the product sheets, they are manufactured by the "Environmental Inks and Coatings Corp." which implies some degree of environmental compatibility.

There is no bulk storage of solvents, oils, or other hazardous substances within the building. The working drums are stored in such a manner that physical damage or spillage is not likely. Even if a drum were to leak, the broad expanse of level concrete floor would preclude run off outside the building. Such spillage could be controlled by absorbents. As part of our Article XII report, we will be specifying proper storage and containment for future bulk quantities.

Operations within the warehouse appear very tidy, and our client is making a bona fide effort to operate in accordance with Suffolk regulations.

Yours truly,

HOLZMACHER, McLENDON & MURRELL, P.C.

Hugo D. Freudenthal, Ph.D.

Re: Commercial Envelope Manufacturing Co.

Dear Mr. Creditor:

Together with one of our engineers, we made a preliminary inspection of the Commercial Envelope Manufacturing facility on Friday, October 19. At that time we observed water oozing from the ground in the vicinity of the alleged air conditioner leaching basin. Aside from standing surface water in the vicinity of the pits east of the incinerator, there appeared to be no other discharged water.

Yesterday I received a call from Ms. Joanne Johnson of the Suffolk County Health Department, requesting that we visit the plant together. We arrived there at 1 PM. The previous night there had been heavy rain.

We observed purple colored water bubbling up from one of the pits, and the surrounding ground was flooded. The bubbling up water could not have come from standing stormwater, because the water elevation in the surrounding storm basins was several feet below grade. Clear water was sheeting out from the air conditioner basin. Water was trickling out of the two roof drains on to the ground.

In my presence Ms. Johnson dye tested the hand-wash sink in the factory and the sump in the photo room. Dye did not appear in either the purple effluent or in the inside holding tank. We spent considerable time trying to trace waste lines, but we could not account for the disappearance of the dye.

Ms. Johnson gave me copies of the organic analyses of water taken from the pits (the county is sending you copies by registered mail). High concentrations of organic solvents are shown, of the types used in printing inks. She told me that she called the manufacturers of the inks used, and none of them manufacture water based inks. I suspect that the inks that you are using may be of an emulsion type which is miscible with water, but which still contain organic components. I have asked Mr. Brannigan to obtain the specification sheets on all of the products used, and I urge you to expedite this. If he is unable, we will inventory the materials and

contact the manufacturer. This information must be included in the report.

Commercial Envelope has a serious problem with the existing pools. There is definitely an illegal discharge! As it claimed that the factory is not utilizing the pools, I urge the company to immediately engage the services of a licensed industrial waste contractor to properly remove the material therein and fill the pools. Failure to secure the pools can only result in future violations. As the work will have to be done eventually, it would be advantageous to do it right now!

The contractor must also excavate and trace any waste line back to the building, so that the discharge from the sinks can be found. It is important that we and the County be notified when this work is to take place so that the proper observations can be made.

We have some more work to do in accounting for the discharges, which are not as evident as originally presumed. After the excavation and the completion of our inventory, we should get together for a progress meeting.

Yours truly,

HOLZMACHER, McLENDON & MURRELL, P.C.

Inspection of Commercial Envelope Mfg. for "certificate to operate" "liquid waste incinerator."

I was accompanied on my inspection by, a Mr. Leroy Brannigan of Commercial Envelope. We inspected the waste incinerator, the waste holding tank, + the two general sources of waste to the tank.

At the location of the "wet scrubber" I noticed a circular area of 1-2" pipe with the pipe stick up up approx. 6-8", + I asked Mr. Brannigan if the use of the pipe that the water had discharged into. He went under the floor (in the shed) and had discovered into leaching pits that had been covered + filled. Mr. Brannigan said "Yes" that was the discharge site.

SPECIAL NOTE: ! !

While dye testing the pipe that connected the ~~rock~~ "ink pot" wash machine to a leaching pool, which is located on the East side of Commercial Envelope Mfg Corp. some difficulty was encountered. Two bottles of dye (250ml.) had been inserted into a pipe located adjacent to the "ink pot" wash machine. [This same pipe had been previously identified to me as discharging into the leaching pool(s) (two pools in line) located on the East side of Commercial Envelope, by Mr. LeRoy Brassington, Manager at Commercial.]
A garden type hose was connected to a nearby hand wash sink, the valve was turned on full, and the end of the hose inserted into the pipe. Within 2-3 minutes the dye (green) was observed at an excavation approx 100 Ft. to the East of the "ink pot" wash machine. [This ~~excavation~~ location was the site of a previous excavation that had resulted in the pipe being cut, (a 32" section was removed, which was later found in the excavation) and plugged with ~~a~~ 4.5" wooden plugs. These plugs had previously been removed prior to sampling the material in the pipes.]
The dyed liquid poured out of the Western unplugged line, flowed across dirt, then entered the Eastern unplugged line. This flow occured for approx. 5 minutes, when we removed the hose from the pipe and reinserted it in the Eastern unplugged line. The Additional green dye was added to the liquid + the flow from the hose continued. - - -

In all the flow into the Eastern end of the line continued for approx. 7-10 minutes. The dye did not appear in any of the exposed pipes in the suspect leaching pool.

Prior to the search liquid had been observed discharging out of the ground approx. 6ft to the west of the suspect leaching pool. It was thought that the discharge was from a broken pipe which had originally exited in the suspect leaching pool. Therefore a excavation was started at that approximate site of the discharge up thru the ground.

The digging proceeding down thru sand and some wooden debris until a pressurized pocket of gas was encountered. Meter reading for LEL went off the scale, and the immediate area was cleared. After approx. 10-15 min. additional reading were taken, the LEL limit was still present, ~~but only at the~~ but significantly lower, digging continued.

The digging continued until an open area underground was encountered. Then a 9" opening in the ground a liquid filled pit was observed. The liquid was "dye green" in color. A 2x4" probe was inserted down approx. 6-8ft. with no bottom encountered. Liquid sampled were removed via a plastic scoop. ~~Because of continued high LEL, Hnu readings the hole was not widened, but was reseated with~~ A 4-6" white pipe was observed crossing over the pit, this pipe was observed discharging "dye green" liquid into the pit liquid at a steady rate. ~~Hnu readings~~

Because of continued elevated LEL readings and steady low O2 readings it was decided not to completely expose the "pit". The hole was ~~extend~~ covered with wood and the sand was replaced into the excavation.

~~The discovery of this additional pollution site~~
The discovery of this unknown "pit" at Commercial Envelope raises some important questions.

1. What is the "pit"?
   - (A) is it a leaching pool?
   - (B) is it a septic tank?
   - (C) is it a holding tank?

Should the SCDHS now require Commercial Envelope to excavate that site fully expose the pit. Identify its nature, and if a pollution site, remove the liquid / sludge present.

Search Warrent Investigation

Personel of the DA's Special Investigation - Environmental Crimes Unit, ie. Investigator Stephen Prelack, + Investigator John Flynn, presented a Warrent for a search at Commercial Envelope Mfg Corp., located at 900 Grand Blvd. Deer Park, NY. The search was to located and dye test particular pipes from the inside of Commercial Envelope, that emanated from the "photo rooms" area and a "ink pot" wash machine. These pipes ~~led~~ led under the floor or ground outside Commercial to the East and ~~had~~ had discharged into a series of two leaching pools. The search also was to conduct sampling of any "sludge" inside those pipes, and liquid from the "ink pot" wash machine, a small collection sump inside the photo rooms, and a "wet" area beneath a loading dock compactor. ~~The~~ The Environmental Crimes Unit was assisted by an additional four investigators, they were to lend a hand excavating the pipes and pools, The additional investigators also shot 35mm prints of the seach, and video taped the sampling.

The identification of particular points to be excavated or sampled was facilitated by personel from the Inspectional Services Section, of the Bureau of Environmental Health ie. Ms. JoAnn Johnson + Mr David Obry ~~[illegible]~~. All samples were to be taken only ~~[illegible]~~ the ~~[illegible]~~ pipes. This identification was ~~[illegible]~~ possible by the more than thirty inspection/sampling conducted by Ms Johnson + Mr Obry at Commercial Envelope prior to the [illegible] by the D.A.

CONTINUED: INSPECTORS OBSERVATIONS OR INTERVIEWS

July 9, 85

The Suffolk County Health Dept. sampling team was Mr. Eric Young, Mr. David Oberg, Mr. [illegible], assisted by Mr. Edwards. Full protective gear was utilized i.e. white hooded protective coveralls, boots, double gloves, SCBA, + two way communications, + LEL/O_2 meters, + lifelines.

The search for the pipes to dye test involved excavation and exposure of two systems discharging into one leaching pool. The line from the "photo rooms" was intercepted as it exited from a cement filled sanitary vault, which is opposite the "photo rooms" on the East outside wall of Commercial. A shallow trench was excavated approx. 3 Ft. wide, 3 Ft. deep + 4-5 Ft. long, this exposed the gray/white composite pipe. Members of the Suffolk County Police-Emergency Service Unit, drilled and chiseled a hole 3" by enough to obtain a sludge sample + to dye test the line.

The pipe from the "ink pot" wash machine, had been previously exposed, cut + plugged inside the printing area. This portion of the pipe was re excavated, & the site was a 4 ft wide x 4 ft long by 4-5 ft deep square hole.

These two pipes ~~exited~~ had previously discharged into a two leaching pools in line, both pools had been ordered pumped + filled in by the SCDHS. The first pool in line with some help from the Babylon Town Highway Dept., was broken open with a jack hammer, and the clean fill previously applied was removed. The leaching pool was excavated down to the 2 discharge pipes, at a dept of approx. 6-7 Ft. below grade.

At that time samples were obtained from the "ink pot" wash machine. On both sides of the plugged line from the "ink pot" machine, and an attempt was made to obtain sludge from the end of the pipe, however none was obtained. From the "photo rooms" area a liquid sample was obtained from a small collection sump along the East wall.

The drilled open "photo room" line was sampled for sludge. The "photo" discharge point in the leaching pool was investigated however there was not sludge to obtain a sample.

A large accumulation of purple liquid inside the loading dock, below the trash compactor, was sampled.

Red dye and approx. 40 gal. of water was inserted into the "dark rm." pipe outside the east side of the Bld. Within approx. 1 min. the red dye appeared inside the leaching pool from a pipe on the NW edge. Green dye and a garden hose on "full" was inserted into a pipe at the "ink pit" wash machine, this green liquid soon appeared at the hole where the pipe was cut and plugged. The liquid soon flowed into the East section of the cut pipe, additional green dye + water via the garden hose was applied to the section, the green dye did not appear at the leaching pool.

An excavation was started approx. 6Ft. West of the leaching pool, hoping to intercept the pipe into the pool. A hole approx 4 ft deep was excavated, at where ~~pipe~~ we discovered a open "pit", with liquid inside, the liquid was ~~gre~~ colored - green" very similar to the dye, a pipe across the opening was observed discharging a small stream into the pit. A 2x4 board was inserted into the pit to a depth of 6-8 below grad, it did not touch bottom. There were explosive gases measured in the pit, a liquid sample ~~was~~ was obtained from the liquid inside the pit, after the gases dispersed.

The samples were preserved by ice, & transported to the WE&S lab & the SCDHS lab in Central Islip.

The entire search was from approx 6AM to 4PM with the after hours.

David Oberg RHS.

COUNTY OF SUFFOLK

PETER F. COHALAN
SUFFOLK COUNTY EXECUTIVE

DEPARTMENT OF HEALTH SERVICES

DAVID HARRIS, M.D., M.P.H.
COMMISSIONER

August 21, 1985

CERTIFIED MAIL R.R.R.

Commercial Envelope Manufacturing Company
900 Grand Boulevard
Deer Park, New York 11729

Attention: Mr. Ira Kristel, President

Gentlemen:

Laboratory analyses of samples removed from Commercial Envelope Manufacturing Company on July 7, 1985 indicate a number of serious potential health problems.

The area below the trash compactor in the loading dock contains liquid which is a combination of rain water and ink waste which spilled from the compactor. The loading dock area had previously been identified to Commercial Envelope as a source of discharge of toxic and hazardous materials. However, actions discussed by Commercial Envelope to control the disposal of ink waste and exposure of the compactor to the weather obviously have not been successful. Therefore, you are directed to have the material (liquid and sludge) tested and removed by an appropriate licensed scavenger.

A second area of concern was discovered close to the two leaching pools located on the east side of Commercial. These two leaching pools had previously been scavenged and filled to grade with sand by Chemical Pollution Control.

Approximately 4 - 5 feet west of the pool identified as Pool #2, the department uncovered a cache of liquid with a depth greater than 8 feet. This liquid was sampled and found to be contaminated with a long list of organic solvents - methylene chloride 180 ppb; 1,1,2 trichloroethylene 33 ppb; p-ethyltoluene 210 ppb; n-decane 190 ppb; n-undecane 130 ppb; cis-dichloroethylene 110 ppb; toluene 970 ppb; ethylbenzene 52 ppb; xylene(s) 500 ppb; 1,3,5 trimethylbenzene 190 ppb; 1,2,4 trimethylbenzene 430 ppb; p-diethylbenzene 98 ppb; 1,2,4,5 tetramethylbenzene 64 ppb.

This cache of unknown liquid must be uncovered for department inspection. The liquid and sludge contained in the cache must be removed by a New York State licensed industrial waste scavenger as soon as possible. The resulting hole must be filled in with clean fill to grade. The Suffolk County Department of Health Services must be notified 72 hours or three working days prior to any work being done so that one of our representatives will be present.

The contaminants in the cache represent unsatisfactory conditions and may constitute violations of the New York State Environmental Conservation Law and Article 12 of the Suffolk County Sanitary Code, which were promulgated to reduce groundwater contamination. Under the Suffolk County Sanitary Code you may be subject to the imposition of a $500 civil penalty each day that these conditions are allowed to remain.

We wish to express our deep concern regarding these conditions, and it is most important that you act expeditiously to eliminate the aforementioned conditions.

Thank you in advance for your prompt attention in this matter.

Very truly yours,

Frank M. Randall
Supervisor
Inspectional Services

15 HORSEBLOCK PLACE • FARMINGVILLE NEW YORK 11738 • (516) 451-4643

In the Matter of the Alleged Violation of Article 12 of the Suffolk County Sanitary Code by Commercial Envelope Mfg. Co. 900 Grand Boulevard Deer Park, NY 11729 Respondent.	ORDER ON CONSENT NO. IW 85-67 DATE: November 12, 1985

GENERAL PROVISIONS

This Department alleges that the above-named Respondent has failed to comply with the provisions of the Suffolk County Sanitary Code as specified below. Because of such alleged non-compliance, the above-named Respondent consents and agrees to the issuance of this Order on Consent, and agrees to be bound by the terms, conditions and provisions stated herein.

Respondent understands that by entering into the Order on Consent with the Department, he is affirmatively and voluntarily waiving his right to a formal adjudicatory proceeding with respect to the matters herein addressed. Although the Department will not pursue further enforcement action with respect to the specific alleged violations of law set forth below if the above-named Respondent enteres into this Order and abides by its terms, Respondent understands that the Department is not agreeing to forbearance from pursuing enforcement action regarding alleged violations not addressed by this Order. Moreover, Respondent understands that notwithstanding his execution of this Order on Consent, his failure to strictly comply with all of the terms, conditions and provisions herein contained will revive the Department's rights regarding the violations alleged as set forth below subject to a set-off for any penalties already paid pursuant to this Order on Consent. Furthermore, the Respondent is hereby advised that this Order on Consent, duly executed by the Respondent's agent and the Commissioner or his duly authorized representative has the force and effect of a Commissioner's Order, the violation of which is subject to penalties as provided in Section 218 of Article 2 of the Suffolk County Sanitary Code. Further, the Department recognizes that there is no admission of fault or guilt by the Respondent concerning any alleged violation of this Order on Consent.

A modification of any of the provisions of this Order on Consent may be obtained by a timely written request demonstrating good and sufficient cause of the change or extension requested. No modification of this Order shall be effective unless and until it is specifically set forth in writing by the Department.

SPECIFICATION OF ALLEGED VIOLATIONS

It is alleged that the Respondent above-named failed to comply with the following provisions of the Suffolk County Sanitary Code as indicated below:

1. On July 7, 1985 - discharge to surface of a toxic or hazardous material (organics - location 3 on Appendix A), in violation of Article 12, Section 1205.

2. As of August 21, 1985 - failure to reclaim, recover and clean up July 7, 1985 discharge (Item 1 above) in violation of Article 12, Section 1217(c).

SPECIFIC TERMS AND CONDITIONS

In satisfaction of the above-named Respondent's alleged violations of the Suffolk County Sanitary Code, the Respondent agrees to the entering and issuance of this Order of the Commissioner of the Suffolk County Department of Health Services, and the Respondent agrees to be bound by the terms and conditions following as well as by the above General Provisions.

LIQUID AND SLUDGE REMOVAL

1. By January 6, 1986 Respondent, as per Article 12, shall have the toxic or hazardous liquid and sludge accummulated in the loading dock area (identified on Appendix A) disposed of by an industrial waste scavenger, licensed by the New York State Department of Environmental Conservation, or by on site incineration if such is acceptable to the New York State Department of Environmental Conservation.

2. Respondent shall notify the Department at least two working days (Monday through Friday) in advance of any testing or disposal of the liquid and sludge referred to in Item 1.

3. By January 6, 1986 Respondent shall have the liquid and sludge below the area identified as (3) on Appendix A, disposed of in accordance with Items 1 and 2 above.

4. Immediately upon completion of Item 3 above, Respondent shall have the area identified as (3) on Appendix A filled to grade with clean sand.

5. By January 6, 1986 Respondent shall provide documentation or sample results that show the three (3) underground ink waste tanks identified as such on Appendix A have been properly abandoned in accordance with Article 12. If the Department finds abandonment was improperly done, Respondent shall remove

SPECIFIC TERMS AND CONDITIONS
(continued)

all material from the three tanks.

6. Immediately upon completion of Item 5 above, Respondent shall have the material so removed, if such is necessary, in accordance with the procedures listed in Items 1 and 2 above.

TOXIC OR HAZARDOUS CHEMICALS REGISTRATION

7. By Jan. 6, 1985 Respondent shall have submitted to the Department an approvable engineering report which details all toxic or hazardous materials being used or stored at the Respondent's facility.

8. The report specified in Item 7 above shall include approvable engineering plans together with application(s) for "Permit(s) to Construct an Above/Underground Toxic or Hazardous Liquid Storage Facility", to bring Respondent's facility into full compliance with Article 12 of the Suffolk County Sanitary Code.

9. The report specified in Item 7 above shall include a completed "Toxic Liquid Storage Registration Form", together with the appropriate registration fee.

10. Respondent shall complete construction in accordance with the approved permit to construct referred to in Item 8 above, on or before the expiration date of said permit.

11. Respondent shall notify the Department for the purpose of inspecting the completed construction referred to in Item 10 above.

12. Any questions concerning Article 12 or testing methods should be addressed to Mr. Vincent Frisina, P.E., of this Department at telephone number (516) 451-4649.

WASTE INCINERATOR

13. Immediately, Respondent shall take all necessary steps to insure that Respondent's industrial waste holding tank and incinerator comply with all applicable state regulations.

GROUNDWATER QUALITY STUDY

14. By December 2, 1985 Respondent shall submit a written proposal to this Department for determining the quality of groundwater which exists at 900 Grand Boulevard in Deer Park, New York, hereinafter known as the site, and downstream in the direction of groundwater flow from the aforementioned site.

SPECIFIC TERMS AND CONDITIONS
(continued)

15. The above proposal shall provide for the installation of groundwater monitoring wells. These wells shall be installed so as to intersect the groundwater and allow sampling of same for organic solvents and metals.

16. Within sixty (60) days of Department's written approval of the aforementioned proposal, all monitoring wells are to be installed in accordance with the proposal as approved by the Department, and groundwater samples, from these wells, submitted to a New York State certified laboratory. Initial samples are to be analyzed for organic solvents and metals.

17. Within one hundred twenty (120) days of Department's written approval of the Respondent's proposal, the Respondent shall have submitted its finalized report on the quality and direction of groundwater flow at the site.

18. The report referred to in Item 17 above shall contain all laboratory analysis results of water samples taken from the monitoring wells, and the absolute groundwater elevation above mean sea level of each well.

19. If a plume of contamination attributable to site activities is found to exist, then the Respondent shall submit a proposal for defining the vertical and horizontal extent of this plume and its chemical constituents.

20. The above proposal and report shall be prepared by qualified groundwater hydrogeologist who has experience in performing an investigation for determining the existence of contamination in the groundwater.

21. The aforementioned proposal and report, as well as any questions concerning it, should be addressed to Mr. James Maloney, P.E., Suffolk County Department of Health Services, 15 Horseblock Place, Farmingville, New York 11738.

22. The Respondent agrees to permit the Department representatives access to the wells for the purpose of obtaining water samples, and to aid the Department, if necessary, in obtaining water from the wells upon reasonable notice.

Pardon the delay on replys to questions on PO - Industrial Waste Incinerator.

① As per conversation with Mr. Gary Miller - representative of H&H, who filled out applications. The unit fires the waste into the flame thru a nozzle.

Therefore it would appear that Commercial requires a Permit as an industrial waste treatment facility. Part 374?

My most recent inspection of the facility Sept. 24, 85, revealed a quantity of cinder like material (clinkers) deposited (thrown) on the surface below the unit. I had some suspicions that this material might be from the incinerator unit. In conversations with Mr. Miller of H&H I mentioned the possibility of solid waste from the unit when it is cleaned. He mentioned that he had observed some "black" clinker like material extracted from the unit, in his presence, when he was on site to inspect the unit. I mentioned that this material is an industrial waste and should be handled in an appropriate manner until its constituents can be ascertained. We agreed that at least one TCLP test should be run on the material prior to that it should be containerized.

SECOND NOTICE

September 26, 1985

Commercial Envelope Manufacturing Corp.
900 Grand Boulevard
Deer Park, New York 11729

Attention: Mr. Ira Kristal, President

Re: Pump Out of Contaminated Liquid

Gentlemen:

On July 7, 1985, samples taken from the underground cache of liquid on the east side of your building were collected by a representative of this department. The laboratory analysis performed by this department revealed that the liquid contained the following:

Methylene chloride	180 ppb	Ethylbenzene	52 ppb
1,1,2 Trichloroethylene	33 ppb	Xylene(s)	500 ppb
p-Ethyltoluene	210 ppb	1,3,5 Trimethylbenzene	190 ppb
n-Undecane	130 ppb	1,2,4 Trimethylbenzene	430 ppb
n-Decane	190 ppb	p-Diethylbenzene	98 ppb
cis-Dichloroethylene	110 ppb	1,2,4,5 Tetramethylbenzene	64 ppb
Toluene	970 ppb		

Due to the toxic nature of this discharge, you are again directed to have the aforementioned liquid immediately pumped and sludge removed by an industrial waste scavenger. The resulting hole must be filled in with clean fill to grade. A list of approved scavengers may be obtained by calling the Office of Solid Waste of the New York State Department of Environmental Conservation, telephone number 516-751-7900. Please note: That each day these contaminants are allowed to leach out of the pool, you may be subject to a $500 civil penalty under the Suffolk County Sanitary Code.

(continued . . .)

You are directed to notify this office at least three (3) weekdays (Monday through Friday) prior to the pumping of these pools so that an inspector may witness this operation. Please note that the hiring of a cesspool pumping service which is not licensed to haul toxic industrial waste is a violation of State and County law and may subject both you and the non-licensed hauler to civil liability (fines). It is your responsibility to determine if the scavenger is licensed to haul industrial waste.

You should also note that scavenger fees for removal of toxic materials may vary between scavengers. You may wish to secure written estimates for your clean out. However, this is not to be construed that the department will accept tardiness in your getting the contaminated leaching facility cleaned out.

If you have any questions, please call me at 516-451-4628.

Very truly yours,

Frank M. Randall
Supervisor
Inspectional Services

GEOHYDROLOGY

GEOLOGY AND AQUIFERS

Unconsolidated deposits, ranging in age from Late Cretaceous to Pleistocene, underlie the mid-island area. These deposits contain several major aquifers and constitute the ground-water reservoir. Thin surficial Holocene deposits of soil and some swamp accumulations occur from place to place, but these are of little significance to the ground-water reservoir. The unconsolidated deposits rest unconformably on crystalline bedrock consisting of Precambrian (?) schist and gneiss which is considered to be the bottom of the ground-water reservoir on Long Island.

The unconsolidated deposits, from the bedrock upward, include the Lloyd Sand Member and clay member of the Raritan Formation of Late Cretaceous age, the Matawan Group-Magothy Formation, undifferentiated, also of Late Cretaceous age, and glacial deposits of Pleistocene age. The major aquifers in the area are the deposits of sand and gravel in the Pleistocene and the Matawan-Magothy strata. The test drilling described previously was carried out mostly to the depth of the upper part of the clay member. Therefore, the drilling served to determine the base of the Matawan-Magothy deposits. The drilling also served to obtain information on the configuration of the top of the Matawan-Magothy deposits, which were deeply eroded during Tertiary and, probably, Pleistocene time.

BEDROCK OF THE PRECAMBRIAN (?) SYSTEM

The Precambrian (?) gneiss and schist which underlies Long Island is hard and dense. Virtually all the water in these rocks is found in joints, faults, and foliation planes. Because these openings are usually tight and poorly connected, the bedrock is practically impermeable, especially by comparison with the overlying unconsolidated formations. No wells are known to tap bedrock in the mid-island area.

The bedrock was eroded to a peneplain prior to the deposition of the Cretaceous strata. In the mid-island area, the bedrock surface dips gently southeast at an average slope of about 65 feet per mile (about two-thirds of a degree), and its altitude ranges from about 800 feet below sea level in the northwestern corner of the area to about 1,600 feet below sea level in the southeastern part (pl. 2).

3513

UPPER CRETACEOUS SERIES

Raritan Formation

Lloyd Sand Member

The Lloyd Sand Member of the Raritan Formation comprises the Lloyd aquifer on Long Island. This unit consists mostly of beds and lenses of light- to medium-gray sand and gravelly sand, commonly containing small to large amounts of interstitial clay and silt, that are intercalated with beds and lenses of light- to dark-gray clay, silt, and clayey and silty sand.

Only two drill holes are known to have penetrated the Lloyd in the mid-island area. One hole partly penetrated the unit at the Pilgrim State Hospital, in Brentwood. The second hole, which is in the village of Lake Ronkonkoma, and which was one of the test holes drilled as part of this study, fully penetrated the unit. A log of the test hole describing lithology of the Lloyd is shown in table 1, S33379.

The surface of the Lloyd is roughly parallel to the bedrock surface. The Lloyd surface dips from an altitude of about 550 feet below sea level in the northwestern part of the area, to an altitude of about 1,250 feet below sea level in the southeastern part (pl. 2), and the unit's thickness ranges from about 260 feet to 360 feet from northwest to southeast, respectively. Plate 2 shows contours on the Lloyd surface. Plate 2 also shows contours on the bedrock surface; therefore, the Lloyd's thickness, in any part of the area, can be estimated by computing the local difference between the altitudes of the bedrock and Lloyd surfaces.

The Lloyd aquifer is moderately permeable. Its average horizontal permeability has been estimated by Lusczynski and Swarzenski (1966, p. 19), Isbister (1966, p. 20), and Soren (in press) to range between 400 and 500 gpd per sq ft (gallons per day per square foot) in Queens and Nassau Counties, west of the mid-island area. Warren and others (1968, p. 102) estimated the Lloyd's horizontal permeability to be 165 gpd per sq ft at the Brookhaven National Laboratory, about 12 miles east of the mid-island area. The section of Lloyd penetrated by the test well near Lake Ronkonkoma was fairly sandy and gravelly (table 1, S33379), and at this site the average horizontal permeability of the Lloyd probably is considerably more than 500 gpd per sq ft. Wells tapping the Lloyd in other parts of Long Island have been pumped at rates of as much as 1,600 gpm (gallons per minute), and the specific capacities of these wells (pumpage, in gallons per minute, divided by drawdown, in feet) have been reported to range from 3 to 40 gpm per foot of drawdown.

At present, there is no pumpage from the Lloyd aquifer in the mid-island area, mainly because of the great depth of the aquifer, and because more permeable aquifers are found at shallower depths. In addition to being at a greater depth, the water from the Lloyd commonly has undesirably high concentrations of iron.

Clay Member

The clay member of the Raritan Formation (commonly referred to as the Raritan clay) completely covers the underlying Lloyd aquifer in the mid-island area, and confines water in that aquifer. The Raritan clay consists mostly of beds and lenses of light- to dark-gray clay, silt, and clayey and silty fine sand (table 1). Thin to thick sandy beds commonly occur in the unit from place to place, but these beds do not have great lateral extent. Laminae and thin beds of lignite and pyrite and disseminated particles of these substances are common in the clay beds of the unit. The thickness of the Raritan clay increases to the southeast, and ranges from about 150 feet in the northwestern part of the mid-island area to about 200 feet in the southeastern part.

The surface of the Raritan clay is roughly parallel to that of the underlying Lloyd Sand Member. The altitude of the surface of the Raritan clay ranges from about 300 feet below sea level in the northwestern part of the mid-island area, to about 1,050 feet below sea level in the southeastern part (pl. 3).

Matawan Group-Magothy Formation, Undifferentiated

The Matawan Group-Magothy Formation, undifferentiated, comprises the Magothy aquifer of Long Island. Deposits in this unit consist of beds and lenses of light-gray fine to coarse sand, containing traces to large amounts of interstitial clay and silt, intercalated with thin to thick beds and lenses of light- to dark-gray clay, silt, and clayey and silty sand (table 1). The clay and silt beds commonly contain laminae and thin beds of lignite. Disseminated lignite and pyrite also are common in the sand beds of the aquifer. Gravelly coarse sand is commonly found in the basal part of the aquifer. This coarse zone ranges in thickness from 100 to 150 feet west of the mid-island area to 150 to 200 feet in the mid-island area. The basal zone also commonly contains abundant interstitial clay and silt and many thin to thick beds and lenses of clay, silt, and clayey and silty sand.

The surface of the Magothy aquifer (pl. 4) is not planar as are the surfaces of the underlying units. The Magothy surface was deeply eroded during Tertiary time, and probably was considerably eroded in Pleistocene time. Consequently, the depth to the Magothy aquifer and the aquifer's thickness cannot be predicted as accurately as the depths and thicknesses of the underlying units. Many control points in addition to those already known are needed to accurately map the upper surface of the Magothy aquifer.

The highly irregular character of the surface of the Magothy aquifer is shown in plate 4. The upper surface of the aquifer ranges in altitude from as high as about 200 feet above sea level to as low as about 500 feet below sea level. The Magothy was completely removed by erosion in a buried valley near the South Huntington area, and in that area upper Pleistocene deposits lie directly on the Raritan clay. This buried valley was called the "Huntington buried valley" by Lubke (1964, pl. 3), and as mapped by Lubke, the valley extended about 2-1/2 miles south of the Northern State Parkway.

source of the rock materials in the outwash deposits is manifold. As the glaciers moved southward to Long Island, they plucked the bedrock and soils of the surfaces they slid over. Rock materials were incorporated into the ice in contact zones and were also pushed along the glacial front. As the ice melted in late Pleistocene time, the various rock materials were carried away by broad coalescing streams and sheets of water. Consequently, the outwash deposits are stratified, and because of the varied materials carried by the glacier, these deposits consist of a heterogeneous suite of rock types. The great diversity of rock and mineral suites in the Pleistocene deposits, along with the chemically unstable (easily decomposed) rocks and minerals, commonly facilitates differentiation of glacial from the Cretaceous deposits on Long Island.

Outwash deposits underlie the plain in the mid-island area south of the Ronkonkoma terminal moraine, where the major source of glacial deposition was material from the Ronkonkoma ice advance. A readvance of the glacial front followed recession of the Ronkonkoma ice front and resulted in the formation of the Harbor Hill terminal moraine. Lakes were formed in depressions and valleys between the Ronkonkoma and Harbor Hill terminal moraines, and clayey materials were deposited in these lakes. The intermorainal areas also contain recessional deposits of outwash and ground moraine (see the following section, "Ground-Moraine Deposits") from the Ronkonkoma and Harbor Hill deglaciations, and these materials buried the clayey lake deposits.

The outwash deposits are thickest in the buried valleys and thinnest where the Cretaceous surface is closest to land surface (pl. 5). These deposits generally extend below the water table, and are a major source of ground water. Outwash deposits comprise most of the so-called upper glacial aquifer of Long Island, and because these deposits of sand and gravel contain virtually no interstitial clay and silt, the upper glacial aquifer is the most permeable aquifer on Long Island. The estimated average horizontal permeability of the outwash deposits is about 1,000 to 1,500 gpd per sq ft (Lusczynski and Swarzenski, 1966, p. 17; and Soren, in press). Warren and others (1968, p. 75) computed the horizontal permeability of outwash to be about 1,300 gpd per sq ft at the Brookhaven National Laboratory, east of the mid-island area. A horizontal permeability for outwash as high as about 2,500 gpd per sq ft has been reported in Nassau County, west of the project area (Isbister, 1966, p. 29).

Public-supply and other high-capacity wells screened in glacial outwash on Long Island have yielded as much as 1,700 gpm, and reported specific capacities of such wells range from less than 10 gpm per foot of drawdown to as much as about 200 gpm per foot of drawdown; however, the specific capacities range mostly from 50 to 100 gpm per foot of drawdown. (See section "Yields of Individual Wells.")

the shorelines, the direction of flow is reversed, and ground-water movement is upward from the deeper aquifers toward the surface. Thus, because of the character of the flow system, under natural conditions virtually all the recharge to the Magothy and Lloyd aquifers in western Suffolk County originated in the mid-island area, and all of that recharge ultimately discharged from the ground-water system near the shorelines.

The movement of ground water through Long Island's aquifers in the horizontal direction is generally more rapid than movement in the vertical direction because of the occurrence of interbedded fine- and coarse-grained layers, and because the largest dimensions of unevenly shaped particles in the individual layers tend to be oriented horizontally. Approximate rates of ground-water movement can be computed from hydraulic gradients and estimated coefficients of permeability and porosities of the aquifers. In 1968, water in the upper glacial aquifers in the project area was moving horizontally at rates from less than 0.5 foot per day at points distant from centers of pumping, to hundreds of feet per day near the screens of pumping wells. At the same time, water in the Magothy aquifer was moving horizontally at rates from less than 0.2 foot per day at points distant from pumping, to hundreds of feet per day near the screens of pumping wells.

HYDRAULIC INTERCONNECTION OF AQUIFERS

The aquifers of Long Island are hydraulically interconnected. Layers of clay and silt within an aquifer or between aquifers serve to confine water below them, but they do not completely prevent the vertical movement of water through them. Ground water moves downward readily through coarse outwash deposits in the upper glacial aquifer. Vertical movement of water through the Magothy aquifer is impeded by beds and lenses of clay and silt. Because the clay and silt strata in the Magothy are not continuous, some water may move around lenses of this material in addition to moving slowly through the fine-grained strata.

The contact between the upper glacial and Magothy aquifers is not regular either in attitude or in composition of the contact surfaces. Glacial deposits in buried valleys are in lateral contact with truncated sandy beds in the Magothy. In the buried valleys water can laterally enter the Magothy at great depth directly from the glacial deposits, rather than the water having to move vertically to the same depth through less permeable Magothy beds. In the Huntington buried valley, glacial deposits extend completely through the Magothy aquifer to the underlying Raritan clay. (See plate 4.) In addition to the good hydraulic continuity between the upper glacial and Magothy aquifers in the buried valleys, good hydraulic continuity occurs between the aquifers outside the buried valleys where glacial sand and gravel deposits lie directly on Magothy sand beds. Thus, a fairly good hydraulic connection exists between the upper glacial and Magothy aquifers over large parts of the mid-island area, and the configuration of the piezometric surface of the Magothy aquifer is generally similar to that of the water table. However, in the mid-island area hydraulic heads in the Magothy are lower than those in the upper glacial aquifer because of the downward component of ground-water movement in the area.

The thick areally persistent Raritan clay that lies between the Magothy and Lloyd aquifers impedes but does not prevent downward movement of ground water into the Lloyd aquifer, and water in the Lloyd is tightly confined between the Raritan clay and bedrock. Downward leakage into the bedrock is negligible.

Figures 2 and 3 show hydrographs of wells screened in the upper glacial aquifer and the Magothy aquifer at the test-drilling sites in Brentwood and Hauppauge. At both sites, the heads in the deepest wells in the Magothy aquifer are about 2.5 to 3 feet lower than the heads in the shallowest wells in the upper glacial aquifer. The loss of head downward reflects the downward movement of ground water in the mid-island area. The hydrographs in figures 2 and 3 show that the heads in these two aquifers in the project area decrease at a fairly uniform rate with increasing depth. In addition, water-level fluctuations in the two groups of wells were very similar. Both of these facts, the uniform decrease in head and the similar water-level fluctuations, reflect the high degree of hydraulic interconnection between the upper glacial and Magothy aquifers.

The average vertical permeability of the Magothy aquifer is only poorly known. Estimates range from less than 1 to about 30 gpd per sq ft. Assuming that it averages about 5 gpd per sq ft in the mid-island area, the computed amount of downward ground-water movement through the Magothy aquifer in the vicinity of the ground-water divide in 1968 was about 0.4 mgd (million gallons per day) per square mile, and the estimated velocity of the downward movement was about 0.006 foot per day.

Because of the low permeability of the Raritan clay, the hydraulic-head loss across this unit is very much larger than the head loss across a comparable thickness of the Magothy and upper glacial aquifers. At the easternmost test site in the village of Lake Ronkonkoma, wells were screened near the base of the Magothy and near the top of the Lloyd aquifers (pl. 5, section A-A', S33379-80). In 1968, the head near the base of the Magothy aquifer (about 45.5 feet above sea level) was about 11.5 feet higher than the head in the Lloyd aquifer (about 34 feet above sea level). Head losses across the Raritan clay at localities east and west of the Lake Ronkonkoma area differ considerably. At Upton, about 12 miles east of the mid-island area, the head loss across the clay was about 6 feet in 1968; and at Plainview (in Nassau County), about 3 miles southwest of Melville, the head loss across the clay was about 42 feet. The differences in head loss from place to place are largely a result of differences in the vertical permeability and thickness of the Raritan clay.

The head in the Lloyd aquifer at Lake Ronkonkoma in 1968 (about 34 feet above sea level) was higher than either of the heads in the Lloyd at Upton (about 30.5 feet above sea level) and at the Suffolk-Nassau boundary (about 27.5 feet above sea level). The head in the Lloyd at Terryville, about 7 miles northeast of the Ronkonkoma area was about 21 feet above sea level in 1968, and it was 19 feet above sea level at Fire Island State Park in 1968, about 13 miles to the southwest. These data suggest that water in the Lloyd aquifer is moving radially from the Lake Ronkonkoma area. The estimated rate of horizontal movement of water in the Lloyd aquifer in the project area in 1968, was on the order of 0.1 foot per day.

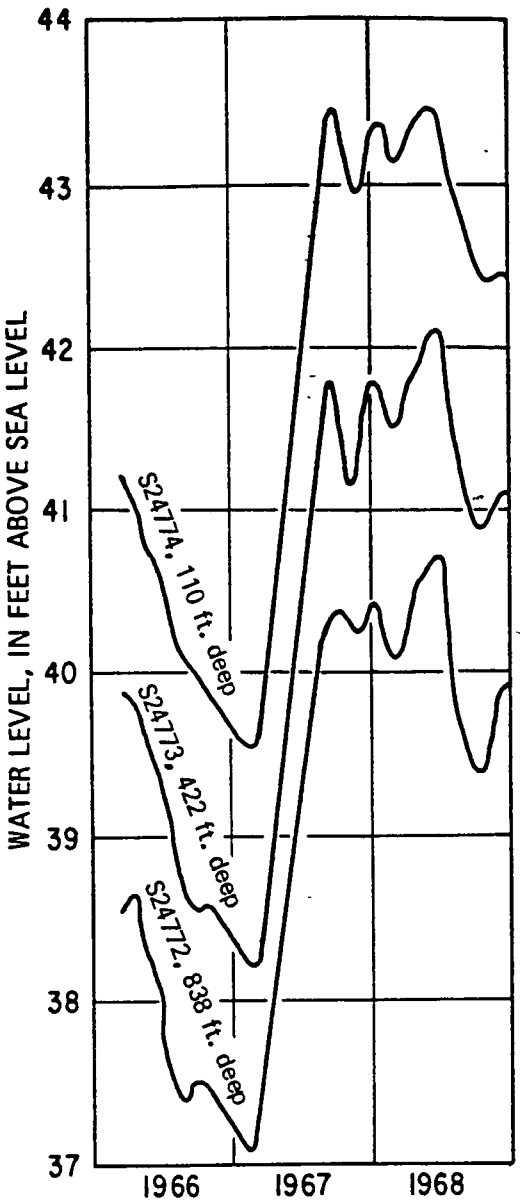

Figure 2.--Fluctuations of water levels in wells screened in the upper glacial aquifer and the Magothy aquifer at Brentwood, N. Y.

FLUCTUATIONS OF GROUND-WATER LEVELS

Fluctuations of water levels in the wells of the mid-island area reflect local variations in recharge to and discharge from the aquifers tapped by the wells. Therefore, changes in ground-water levels afford an insight into many aspects of the ground-water system. Furthermore, the information on water-level fluctuations can be used to help assess the impact of urbanization on the natural hydrologic system.

9613

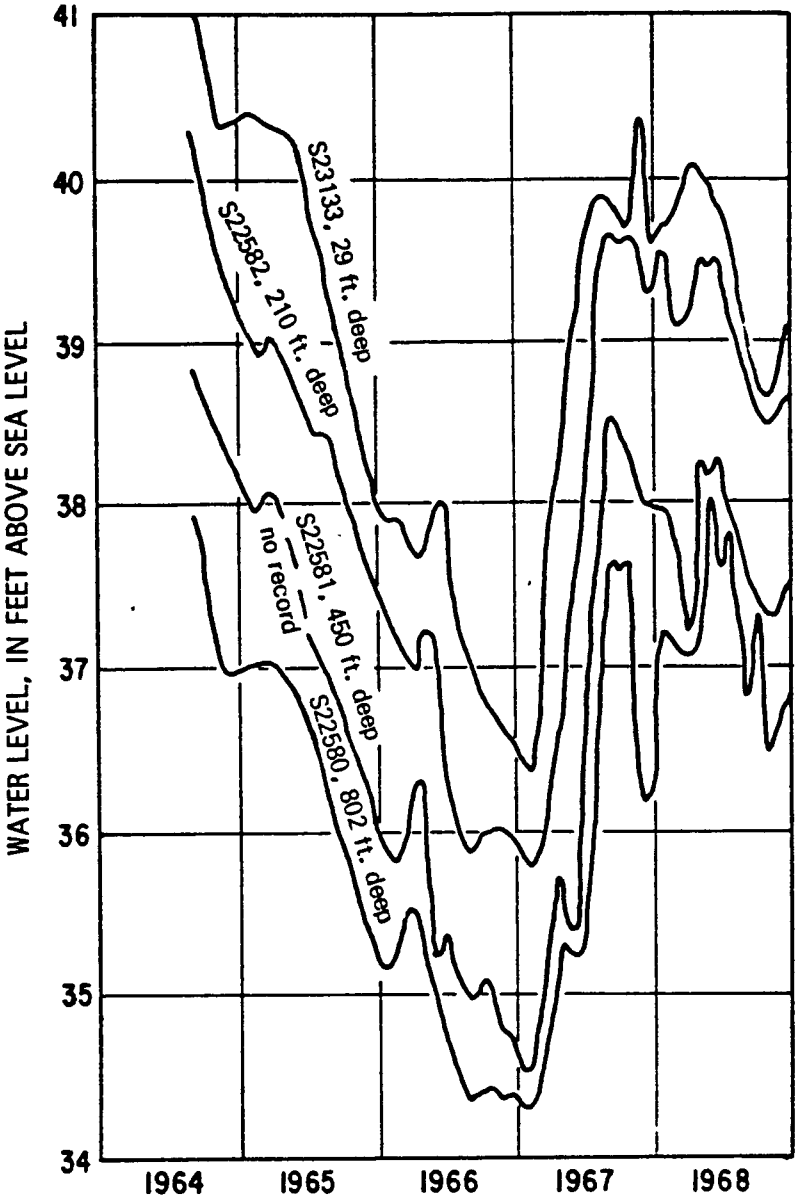

Figure 3.--Fluctuations of water levels in wells screened in the upper glacial aquifer and the Magothy aquifer at Hauppauge, N. Y.

Under natural conditions and in relatively undeveloped areas of Long Island, the water table fluctuates over a range of several feet during the year. Under such conditions, the water table has a rhythmic seasonal pattern; the lowest levels are in late autumn and highest levels are in early spring. This pattern of decline and recovery of the water table reflects the greatest losses of water through evapotranspiration during the growing season and the least such losses between growing seasons. The hydrologic systems in such undeveloped areas are in equilibrium, with inflow balancing outflow. However, if large amounts of water are continually pumped out of a ground-water system, the water table declines until equilibrium is reestablished at a lower level, reflecting a loss of ground water from storage and decreased subsurface and stream outflow from the system.

Appendix 1.3-3

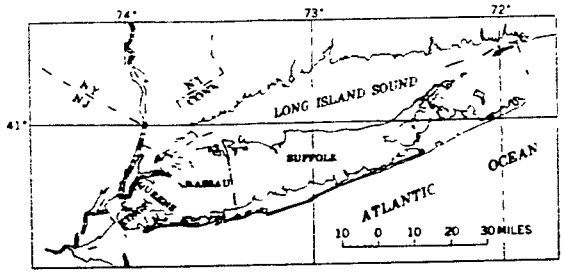
Hydrology of Suffolk County, Long Island, NY

Jensen & Soren, 1974

INTRODUCTION

WATER NEEDS OF SUFFOLK COUNTY

Water pumped from aquifers underlying Suffolk County (index map) is the sole source of water used for public supply, agriculture and industry. The county's population grew from less than 200,000 in 1940 to 1.1 million in 1970. Most of the growth occurred after 1950. Ground-water pumpage increased from 40 mgd (million gallons per day) in 1950 to 155 mgd in 1970 (New York State Department of Environmental Conservation, written commun., June 1, 1971). The projected ground-water use for an anticipated population of 2 million in the county by 1990 is 300 mgd (New York State Conservation Department, 1970, p. 26–27).



INDEX MAP SHOWING LOCATION (SHADED) OF SUFFOLK COUNTY

PURPOSE AND SCOPE

The large and growing demand for ground water in Suffolk County has created a need for a detailed knowledge of the geometry and the hydrologic characteristics of the ground-water reservoir. Mapping of subsurface geology and hydraulic heads in the aquifers are important prerequisites to obtaining this information. Maps of the subsurface geologic units of Long Island were first shown in a report by Suter and others (1949, pls. VIII to XXI). But those maps were highly generalized because there were few data on deep borings and wells in the county when the report was prepared. Since 1949 additional data from many deep borings and wells in the county have been collected.

In 1968, as part of a continuing cooperative program of water-resources studies with the Suffolk County Water Authority and Suffolk County Department of Environmental Control, the U.S. Geological Survey began an updating of the hydrogeologic and hydrologic maps of all the county. The basic data in Jensen and Soren (1971) the first product of the program, are the basis for the hydrologic maps in this report.

ACKNOWLEDGMENTS

The authors appreciate the cooperation of well-drilling companies, their employees and the many officials of public and private water companies who furnished geologic and hydrologic data for use in this report.

GEOLOGIC AND HYDROGEOLOGIC UNITS

Pleistocene glacial drift generally mantles the county's surface. Pleistocene deposits overlie unconsolidated deposits of Late Cretaceous age. The Cretaceous strata lie on a peneplain that was developed on Precambrian(?) crystalline rocks.

Major landforms include ridges, valleys, and plains. These landforms are roughly oriented in belts parallel to the county's length. The northern and the central parts are traversed by irregular sandy and gravelly ridges of terminal moraine. The crest of the northern ridge ranges in height from 100 to 300 feet above sea level and the crest of the central ridge from 150 to 400 feet. The highest altitudes in the inter-ridge area range from 100 to 200 feet. Irregular plains and rolling hills formed from sandy and gravelly ground moraine and outwash deposits of sand and gravel lie in the area between the ridges. An outwash plain slopes at a near-uniform gradient from the southern base of the central ridge, which is about 100 feet above sea level, southward to Great South Bay and the ocean. Along the north shore, steep bluffs as high as 100 feet and generally narrow sandy and gravelly beaches face Long Island Sound. The barrier-bar system at the southernmost side of the county is composed of sandy beach and dune deposits. The highest altitudes of the barrier bars generally range from 10 to 45 feet.

The ground-water reservoir system of Suffolk County is composed of hydrogeologic units that include lenses and layers of clay, silt, clayey and silty sand, sand, and gravel. A hydrogeologic unit consists of a geologic unit or a group of contiguous geologic units classified by hydraulic characteristics. These units include aquifers which are principal water sources and confining layers which separate the aquifers. The aquifers are, from the land surface downward, the upper glacial aquifer, the Magothy aquifer, and the Lloyd aquifer. The major areal confining layers are, in descending order, the Gardiners Clay, the Monmouth greensand, and the Raritan clay. The base of the ground-water reservoir is the crystalline bedrock. Characteristics of the geologic and the hydrogeologic units are summarized in the table, and the following data of hydrologic significance are shown on the maps: base of ground-water reservoir, altitudes of aquifers, altitudes and limits of confining layers, and distribution of surficial deposits. The hydrogeologic sections show the vertical relations of the units to each other.

The sharp angular shapes of some of the contours reflect the fact that in places the contours are drawn on stratigraphic tops of the hydrogeologic units and in places the contours are drawn on erosional surfaces. The sharp angles result from the juncture of a stratigraphic top and an eroded surface.

foot, and are commonly masked by fluctuations of larger amplitude. Cyclical fluctuations in pressure also result from ocean tides, particularly in wells screened in the intermediate and deep aquifers near Long Island Sound. For example, at well S2020 located on a promontory between Duck Island Harbor and Northport Bay and screened in the deep aquifer, water-level fluctuations caused by tidal loading have a daily amplitude of as much as 3 feet between high and low tide. Tidal changes in Lloyd and Cold Spring Harbors also influence the water levels of wells S9 and S4466, both of which are screened in the deep aquifer.

RECHARGE

All the fresh water in the ground-water reservoir of the project area, as well as the rest of Long Island, is derived from precipitation. However, only a part of the total precipitation that falls reaches the water table. The amount which percolates down to the water table and recharges the reservoir is the residual of the total precipitation not returned to the atmosphere by evapotranspiration or lost to the sea by overland runoff. Owing to the highly pervious nature of the soil and the substrata and to the gentle slopes of the land surface, infiltration is relatively high. Of an average annual precipitation on the project area of 49 inches, 21 inches, or about 43 percent, is estimated to reach the water table.

The catchment surface on which recharge presumably takes place includes most of the land area of the project, or about 146 square miles. This catchment includes Lloyd and Eatons Necks but does not include an additional 7 square miles of high water table and tidal marshes which fringe the northern shoreline. A considerable part of the catchment area, however, is made impervious by buildings and pavements, but much of the runoff from such covered areas is recovered in storm water disposal (recharge) basins or large-diameter diffusion wells. The natural recharge from precipitation on the project area, exclusive of the high water-table areas, the tidal marshes and of Lloyd and Eatons Necks, is estimated to average about 140 mgd (million gallons per day). In addition, the recharge on Lloyd Neck is estimated to average about 5 mgd and on Eatons Neck about 2 mgd. The total for the project area then would be about 147 mgd. The rate of natural recharge varies greatly from season to season and from year to year depending on such factors as evapotranspiration, air and soil temperatures, soil-moisture conditions, and the nature and seasonal distribution of precipitation. During dry years, recharge is substantially less than average, and conversely in wet years it is more.

Natural replenishment of the intermediate and deep aquifers takes place entirely by downward movement of water from the shallow aquifer through discontinuities in clayey and silty beds and probably directly by slow movement through these aquicludes. Recharge of the intermediate aquifer probably occurs chiefly in the areas where the water table lies above an altitude of about 60 feet (pl. 5). The deep aquifer, in turn, receives recharge by downward leakage from the intermediate aquifer through an extensive aquiclude formed chiefly by the clay member of the Raritan formation. This recharge, which probably proceeds at a very slow rate, occurs chiefly where the piezometric surface of the intermediate aquifer lies above an altitude of about 60 feet (fig. 6).

Artificial recharge of the ground-water reservoir is effected by means of cesspools and septic tanks, which ultimately receive most of the water pumped from public-supply and domestic wells. For example, during 1957 an estimated average of about 9.8 mgd was returned to the ground by this means in the project area, and at the same time about 2.5 mgd was discharged directly into Long Island Sound through sewage disposal systems at the villages of Huntington and Northport and at Kings Park State Hospital. Also, as required by law, an average of about 0.7 mgd of water pumped from privately owned wells for industrial and cooling purposes during 1957 was returned to the ground through sumps and diffusion wells.

MOVEMENT

In the ground-water reservoir, water moves vertically and laterally from points of high head to points of low head along flow lines whose direction is normal to the contour lines shown for the water table (pl. 5) and the piezometric surfaces (figs. 6 and 9). Water in the shallow aquifer flows away from the two major highs on the main watertable divide of Long Island, represented by areas above the 70-foot watertable contour in south-central Huntington and eastern Smithtown (pl. 5). The general directions of ground-water flow are north toward the Long Island Sound, south toward the Atlantic Ocean, and also a pronounced lateral movement toward the trough in the valley of the Nissequogue River. Local directions of flow, which may deviate substantially from these general directions, are indicated by arrows on the water-table contours (pl. 5). Also, the peninsulas of Lloyd, Eatons, and Little Necks each contain a groundwater mound in the shallow aquifer and from the crests of these mounds the shallow ground water moves laterally outward to bounding salt-water bodies. Within the area circumscribed by the 60-foot water-table contour (pl. 5), a downward head differential generally exists between the shallow and intermediate aquifers. Conse-

Hydrology of the Babylon-Islip Area Suffolk County Long Island, New York

By E. J. PLUHOWSKI and I. H. KANTROWITZ

GEOLOGICAL SURVEY WATER-SUPPLY PAPER 1768

Prepared in cooperation with the Suffolk County Board of Supervisors, Suffolk County Water Authority, and the New York State Water Resources Commission

UNITED STATES GOVERNMENT PRINTING OFFICE, WASHINGTON : 1964

(Brice, Whitaker, and Sawyer, 1956, p. 32). Infiltration rates apparently depend chiefly on the interval between successive floodings, depth of water, and permeability of the basin surface. There are now more than 80 storm-water recharge basins in the Babylon-Islip area, and the number may be expected to increase as urbanization continues. The effectiveness of the basins as a means of recharging storm water to the ground-water reservoir from a suburban area is probably comparable to that of natural surface conditions prior to urbanization (Brice, Whitaker, and Sawyer, 1956, p. 2).

Public sanitary-sewer systems on Long Island discharge their effluent directly into tidewater. Because there are no such systems in the Babylon-Islip area (1961), theoretically all water withdrawn from the ground-water reservoir is returned to the ground. Two large sewage-leaching beds serve Pilgrim and Central Islip State Hospitals, and several smaller ones are at other institutions. The balance of domestic sewage is returned to the ground through cesspools. Water pumped for industrial purposes is usually returned through diffusion wells and cesspools. A small amount of industrial pumpage containing contaminants is discharged into tidewater to avoid pollution of ground-water supplies.

Artificial recharge in the Babylon-Islip area counters the effect of urbanization by restoring the natural rate of infiltration of precipitation through the use of recharge basins and by returning most of the water pumped.

Because it is not practical to measure directly the rate of recharge to the ground-water reservoir, recharge must be determined by indirect methods. An approximate value for recharge is obtained by subtracting evapotranspiration losses and direct runoff from precipitation. The recharge to the ground-water reservoir in the Babylon Islip area as determined by this method is:

	Approximate annual rate (inches)	
Precipitation		46
Evapotranspiration	21	
Direct runoff	1	
Total water loss		22
Recharge to ground-water reservoir		24

A recharge rate of 24 inches per year is equivalent to 1.1 mgd (million gallons per day) per sq mi or an annual total of about 215 mgd for the Babylon-Islip area. The bulk of this recharge occurs during late fall, winter, and early spring, when evapotranspiration is at a minimum.

Address: _____ Person Making Contact: E. Bidwell

Communications Summary: H_2M has done the engineering work for Dix Hills Water District. There are five wells in our area of concern. Ryder Avenue well S-34022 is 490 feet deep. The Thorngrove well field consists of 2 wells approximately 700 feet deep. Colby Court has one well 605 feet deep. Elkland Road has one well 705 feet deep. All wells are in the Magothy Formation and the entire water district serves 29,415. The system is integrated but due to high and low zones these wells could effectively be isolated.

Communications Summary: The 2 wellfields in our studies pull from the Magothy Aquifer. They own one other well and their system is fully integrated. They currently have 6,500 hookups approximately 26,000 consumers.

They are in the process of installing a system in an Industrial Park. This park will eventually house 150 buildings. The area is bounded on the north by Pilgrim State Hospital, the east by Sagtikos State Parkway, the south by Long Island Railroad and the west by Islip Town Line.

RECEIVED [illegible]

United States
Department of
Agriculture

Soil
Conservation
Service

127 East Main Street
Riverhead, New York 11901

March 13, 1986

Mr. William L. Going, Manager
Environmental Assessment Studies
EA Science and Technology
R.D. 2, Box 91
Middletown, New York 10940

Dear Mr. Going:

This office has not compiled any information on the number of acres irrigated based on specific locations in Suffolk County. The 1982 Census of Agriculture estimates that 23,232 acres are irrigated on 500 farms, however, the specific locations of this acreage is not readily available.

The major source of irrigation water in Suffolk County is groundwater through wells. There are literally thousands of wells scattered throughout the county. To locate wells within a three mile radius of the inactive hazardous waste sites would be an impossible task.

Just to inventory the irrigated acres in proximity to these sites would be very time consuming. I do not have the manpower nor the time at present to accomplish such a task.

I would be more than willing to provide you with access to our aerial photographs, soil maps, topographic surveys and other technical information which might be helpful to you in making this inventory.

If you have any questions or I may be of further assistance, call me at 516-727-2315.

Sincerely,

Allan S. Connell

Allan S. Connell,
District Conservationist

3/28/86 Mr. Connell says that the 23,232 ac/500 farms represent the vast majority ... up to 90% ... for Suffolk Co. and that I can assume all irrigate ... so I will convert ag. land on color plates (land use) to irrigated acreage.
William L. Going

Person Contacted: Mr. Dan Fricke Date: 4-7-86

Phone Number: 516 727 7850 Title: Coop Ext. Ag. Agent

Affiliation: Suffolk Co. Coop Ext. Assn. Type of Contact: Phone

Address: 264 Griffing Ave. Riverhead NY Person Making Contact: Bud

Communications Summary: I asked Dan question about irrigation practices in Suffolk Co. i.e. could Coop Ext. identify sources of irrigation water (well + surface) and tell me for all irrigated ~~crops~~ acreage... which was in food production or dairy farms?

He said that all irrigation wells were supposed to be registered with the State and that perhaps SCDHS had the maps to indicate location and number (Joe Bair?) or (Steve Carey).

* He said there was no surface water used for irrigation on the Island.

He said that once we had located all the wells within required distance of sites; we would have to talk to Coop Ext about each well to find out about the use of the land; very time consuming process.

☒ A ACTIVE ☐ B INACTIVE ☐ C UNKNOWN

03 YEARS OF OPERATION

1976 (BEGINNING YEAR) | present (ENDING YEAR) ☐ UNKNOWN

04 DESCRIPTION OF SUBSTANCES POSSIBLY PRESENT, KNOWN, OR ALLEGED

Printing ink and photo wastes containing mixed heavy metal and solvent wastes discharged to leaching pools. Solvent and lead-contaminated wastes from a trash compactor flowed into a storm drain. Ink wastes were held within below grade tanks. Discharge to a discovered underground "cache" still active,*

05 DESCRIPTION OF POTENTIAL HAZARD TO ENVIRONMENT AND/OR POPULATION

Potential ground-water contamination problem resulting from several years discharge of printing ink and photo waste containing mixed heavy metal and solvent wastes.

V. PRIORITY ASSESSMENT

01 PRIORITY FOR INSPECTION (Check one. If high or medium is checked, complete Part 2 - Waste Information and Part 3 - Description of Hazardous Conditions and Incidents)

☐ A HIGH (Inspection required promptly) ☑ B MEDIUM (Inspection required) ☐ C LOW (Inspect on time available basis) ☐ D NONE (No further action needed; complete current disposition form)

INACTIVE HAZARDOUS WASTE DISPOSAL SITE REPORT

PRIORITY CODE: _____ SITE CODE: 152103

NAME OF SITE: Commercial Envelope Mfg. Co., Inc. REGION: I

STREET ADDRESS: 900 Grand Boulevard

TOWN/CITY: Deer Park COUNTY: Suffolk

NAME OF CURRENT OWNER OF SITE: Town of Babylon Industrial Development Agency

ADDRESS OF CURRENT OWNER OF SITE: 200 E. Sunrise Highway, Lindenhurst, New York 11757

TYPE OF SITE: OPEN DUMP [X] STRUCTURE [X] LAGOON [ ]
LANDFILL [ ] TREATMENT POND [ ]

ESTIMATED SIZE: 1 ACRES

SITE DESCRIPTION:

The envelope manufacturing operation has been active from 1976 until the present and generates various hazardous substances including waste solvents, glues, and ink.

Three areas at the site have been associated with hazardous waste. Three leaching pools received printing ink and photo wastes containing mixed heavy metal and solvent wastes. Solvent and lead-contaminated wastes from a trash compactor flowed into a storm drain. Ink wastes were held in 3 below grade storage tanks.

HAZARDOUS WASTE DISPOSED: CONFIRMED [X] SUSPECTED [ ]

TYPE AND QUANTITY OF HAZARDOUS WASTES DISPOSED:

TYPE	QUANTITY (POUNDS, DRUMS, TONS, GALLONS)
Methylene Chloride	Unknown
Toluene, Xylene,	
Decane, 1,2,4 Trimethylbenzene	
Copper, Iron, Zinc	
Lead, Chromium	

TIME PERIOD SITE WAS USED FOR HAZARDOUS WASTE DISPOSAL:

_____, 19 ___ TO _____, 19 ___

OWNER(S) DURING PERIOD OF USE: Town of Babylon IDA

SITE OPERATOR DURING PERIOD OF USE: Commercial Envelope Mfg. Co., Inc.

ADDRESS OF SITE OPERATOR: Grand Boulevard, Deer Park, New York 11729

ANALYTICAL DATA AVAILABLE: AIR ☐ SURFACE WATER ☐ GROUNDWATER ☐
SOIL [x] SEDIMENT ☐ NONE ☐

CONTRAVENTION OF STANDARDS: GROUNDWATER ☐ DRINKING WATER ☐
SURFACE WATER ☐ AIR ☐

SOIL TYPE: Sand and gravel

DEPTH TO GROUNDWATER TABLE: 30 ft

LEGAL ACTION: TYPE: _____ STATE ☐ FEDERAL ☐
STATUS: IN PROGRESS ☐ COMPLETED [x]
REMEDIAL ACTION: PROPOSED ☐ UNDER DESIGN ☐
IN PROGRESS ☐ COMPLETED ☐

NATURE OF ACTION: _____

ASSESSMENT OF ENVIRONMENTAL PROBLEMS:

Potential ground-water contamination resulting from several years discharge of printing ink and photo waste.

ASSESSMENT OF HEALTH PROBLEMS:

None known or documented.
